# Package 'Seurat'

June 22, 2023

**Version** 4.3.0.1 **Date** 2022-11-18

Title Tools for Single Cell Genomics

Description A toolkit for quality control, analysis, and exploration of single cell RNA sequencing data. 'Seurat' aims to enable users to identify and interpret sources of heterogeneity from single cell transcriptomic measurements, and to integrate diverse types of single cell data. See Satija R, Farrell J, Gennert D, et al (2015) <doi:10.1038/nbt.3192>, Macosko E, Basu A, Satija R, et al (2015) <doi:10.1016/j.cell.2015.05.002>, Stuart T, Butler A, et al (2019) <doi:10.1016/j.cell.2019.05.031>, and Hao, Hao, et al (2020) <doi:10.1101/2020.10.12.335331> for more toils.

Seurat-package

Seurat: Tools for Single Cell Genomics

# Description

A toolkit for quality control, analysis, and exploration of single cell RNA sequencing data. 'Seurat' aims to enable users to identify and interpret sources of heterogeneity from single cell transcriptomic measurements, and to integrate diverse types of single cell data. See Satija R, Farrell J, Gennert D, et al (2015) doi:10.1038/nbt.3192, Macosko E, Basu A, Satija R, et al (2015) doi:10.1016/j.cell.2015.05.002, Stuart T, Butler A, et al (2019) doi:10.1016/j.cell.2019.05.031, and Hao, Hao, et al (2020) doi:10.1101/2020.10.12.335331 for more details.

Seurat-package 7

#### Package options

Seurat uses the following [options()] to configure behaviour:

Seurat.memsafe global option to call gc() after many operations. This can be helpful in cleaning up the memory status of the R session and prevent use of swap space. However, it does add to the computational overhead and setting to FALSE can speed things up if you're working in an environment where RAM availability is not a concern.

Seurat.warn.umap.uwot Show warning about the default backend for RunUMAP changing from Python UMAP via reticulate to UWOT

Seurat.checkdots For functions that have ... as a parameter, this controls the behavior when an item isn't used. Can be one of warn, stop, or silent.

Seurat.limma.wilcox.msg Show message about more efficient Wilcoxon Rank Sum test available via the limma package

Seurat.Rfast2.msg Show message about more efficient Moran's I function available via the Rfast2 package

Seurat.warn.vlnplot.split Show message about changes to default behavior of split/multi violin plots

AddAzimuthResults

Add Azimuth Results

# Description

Add mapping and prediction scores, UMAP embeddings, and imputed assay (if available) from Azimuth to an existing or new Seurat object

### Usage

```
AddAzimuthResults(object = NULL, filename)
```

# Arguments

object A Seurat object

filename Path to Azimuth mapping scores file

#### Value

object with Azimuth results added

```
## Not run:
object <- AddAzimuthResults(object, filename = "azimuth_results.Rds")
## End(Not run)</pre>
```

AddAzimuthScores 9

AddAzimuthScores

Add Azimuth Scores

#### **Description**

Add mapping and prediction scores from Azimuth to a Seurat object

#### Usage

```
AddAzimuthScores(object, filename)
```

### **Arguments**

object A Seurat object

filename Path to Azimuth mapping scores file

#### Value

object with the mapping scores added

# **Examples**

```
## Not run:
object <- AddAzimuthScores(object, filename = "azimuth_pred.tsv")
## End(Not run)</pre>
```

AddModuleScore

Calculate module scores for feature expression programs in single cells

### **Description**

Calculate the average expression levels of each program (cluster) on single cell level, subtracted by the aggregated expression of control feature sets. All analyzed features are binned based on averaged expression, and the control features are randomly selected from each bin.

# Usage

```
AddModuleScore(
object,
features,
pool = NULL,
nbin = 24,
ctrl = 100,
```

10 AddModuleScore

```
k = FALSE,
assay = NULL,
name = "Cluster",
seed = 1,
search = FALSE,
...
)
```

### **Arguments**

| object   | Seurat object                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| features | A list of vectors of features for expression programs; each entry should be a vector of feature names                                                                                                         |
| pool     | List of features to check expression levels against, defaults to rownames( $x = object$ )                                                                                                                     |
| nbin     | Number of bins of aggregate expression levels for all analyzed features                                                                                                                                       |
| ctrl     | Number of control features selected from the same bin per analyzed feature                                                                                                                                    |
| k        | Use feature clusters returned from DoKMeans                                                                                                                                                                   |
| assay    | Name of assay to use                                                                                                                                                                                          |
| name     | Name for the expression programs; will append a number to the end for each entry in features (eg. if features has three programs, the results will be stored as name1, name2, name3, respectively)            |
| seed     | Set a random seed. If NULL, seed is not set.                                                                                                                                                                  |
| search   | Search for symbol synonyms for features in features that don't match features in object? Searches the HGNC's gene names database; see $ \begin{tabular}{ll} UpdateSymbolList for more details \end{tabular} $ |
|          | Extra parameters passed to UpdateSymbolList                                                                                                                                                                   |

#### Value

Returns a Seurat object with module scores added to object meta data; each module is stored as name# for each module program present in features

  name = 'CD_Features'
)
head(x = pbmc_small[])
## End(Not run)
```

 ${\tt AggregateExpression}$ 

Aggregated feature expression by identity class

### **Description**

Returns aggregated (summed) expression values for each identity class

### Usage

```
AggregateExpression(
  object,
  assays = NULL,
  features = NULL,
  return.seurat = FALSE,
  group.by = "ident",
  add.ident = NULL,
  slot = "data",
  verbose = TRUE,
  ...
)
```

# Arguments

object Seurat object

assays Which assays to use. Default is all assays

features Features to analyze. Default is all features in the assay

12 AnchorSet-class

| return.seurat | Whether to return the data as a Seurat object. Default is FALSE                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| group.by      | Categories for grouping (e.g, ident, replicate, celltype); 'ident' by default                                                                                                  |
| add.ident     | (Deprecated) Place an additional label on each cell prior to pseudobulking (very useful if you want to observe cluster pseudobulk values, separated by replicate, for example) |
| slot          | Slot(s) to use; if multiple slots are given, assumed to follow the order of 'assays' (if specified) or object's assays                                                         |
| verbose       | Print messages and show progress bar                                                                                                                                           |
|               | Arguments to be passed to methods such as CreateSeuratObject#'                                                                                                                 |

#### **Details**

If slot is set to 'data', this function assumes that the data has been log normalized and therefore feature values are exponentiated prior to aggregating so that sum is done in non-log space. Otherwise, if slot is set to either 'counts' or 'scale.data', no exponentiation is performed prior to aggregating If return.seurat = TRUE and slot is not 'scale.data', aggregated values are placed in the 'counts' slot of the returned object and the log of aggregated values are placed in the 'data' slot. For the ScaleData is then run on the default assay before returning the object. If return.seurat = TRUE and slot is 'scale.data', the 'counts' slot is left empty, the 'data' slot is filled with NA, and 'scale.data' is set to the aggregated values.

#### Value

Returns a matrix with genes as rows, identity classes as columns. If return.seurat is TRUE, returns an object of class Seurat.

### **Examples**

```
data("pbmc_small")
head(AggregateExpression(object = pbmc_small))
```

| AnchorSet-class | The AnchorSet Class |
|-----------------|---------------------|
|                 |                     |

# Description

The AnchorSet class is an intermediate data storage class that stores the anchors and other related information needed for performing downstream analyses - namely data integration (IntegrateData) and data transfer (TransferData).

AnnotateAnchors 13

#### Slots

```
object.list List of objects used to create anchors

reference.cells List of cell names in the reference dataset - needed when performing data transfer.

reference.objects Position of reference object/s in object.list

query.cells List of cell names in the query dataset - needed when performing data transfer

anchors The anchor matrix. This contains the cell indices of both anchor pair cells, the anchor score, and the index of the original dataset in the object.list for cell1 and cell2 of the anchor.

offsets The offsets used to enable cell look up in downstream functions

anchor.features The features used when performing anchor finding.

neighbors List containing Neighbor objects for reuse later (e.g. mapping)

command Store log of parameters that were used
```

AnnotateAnchors

Add info to anchor matrix

### **Description**

Add info to anchor matrix

### Usage

```
AnnotateAnchors(anchors, vars, slot, ...)
## Default S3 method:
AnnotateAnchors(
  anchors,
  vars = NULL.
  slot = NULL,
  object.list,
  assay = NULL,
## S3 method for class 'IntegrationAnchorSet'
AnnotateAnchors(
  anchors,
  vars = NULL,
  slot = NULL,
  object.list = NULL,
  assay = NULL,
)
```

14 as.CellDataSet

```
## S3 method for class 'TransferAnchorSet'
AnnotateAnchors(
  anchors,
  vars = NULL,
  slot = NULL,
  reference = NULL,
  query = NULL,
  assay = NULL,
  ...
)
```

### **Arguments**

anchors An AnchorSet object

vars Variables to pull for each object via FetchData

slot Slot to pull feature data for

... Arguments passed to other methods

object.list List of Seurat objects

assay Specify the Assay per object if annotating with expression data

reference Reference object used in FindTransferAnchors
query Query object used in FindTransferAnchors

#### Value

Returns the anchor dataframe with additional columns for annotation metadata

as.CellDataSet Convert objects to CellDataSet objects

#### **Description**

Convert objects to CellDataSet objects

### Usage

```
as.CellDataSet(x, ...)
## S3 method for class 'Seurat'
as.CellDataSet(x, assay = NULL, reduction = NULL, ...)
```

# Arguments

x An object to convert to class CellDataSet... Arguments passed to other methods

assay Assay to convert

reduction Name of DimReduc to set to main reducedDim in cds

as.Seurat.CellDataSet 15

```
as.Seurat.CellDataSet Convert objects to Seurat objects
```

# Description

Convert objects to Seurat objects

### Usage

```
## S3 method for class 'CellDataSet'
as.Seurat(x, slot = "counts", assay = "RNA", verbose = TRUE, ...)
## S3 method for class 'SingleCellExperiment'
as.Seurat(
    x,
    counts = "counts",
    data = "logcounts",
    assay = NULL,
    project = "SingleCellExperiment",
    ...
)
```

# Arguments

| project | Project name for new Seurat object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Value

A Seurat object generated from x

# See Also

```
SeuratObject::as.Seurat
```

as.sparse.H5Group

```
as.SingleCellExperiment
```

Convert objects to SingleCellExperiment objects

# Description

Convert objects to SingleCellExperiment objects

# Usage

```
as.SingleCellExperiment(x, ...)
## S3 method for class 'Seurat'
as.SingleCellExperiment(x, assay = NULL, ...)
```

### **Arguments**

x An object to convert to class SingleCellExperiment... Arguments passed to other methodsassay Assays to convert

as.sparse.H5Group

Cast to Sparse

# Description

Cast to Sparse

# Usage

```
## S3 method for class 'H5Group'
as.sparse(x, ...)

## S3 method for class 'Matrix'
as.data.frame(
    x,
    row.names = NULL,
    optional = FALSE,
    ...,
    stringsAsFactors = getOption(x = "stringsAsFactors", default = FALSE)
)
```

Assay-class 17

#### **Arguments**

x An object

... Arguments passed to other methods

row.names NULL or a character vector giving the row names for the data; missing values are

not allowed

optional logical. If TRUE, setting row names and converting column names (to syntac-

tic names: see make.names) is optional. Note that all of R's **base** package as.data.frame() methods use optional only for column names treatment, basically with the meaning of data.frame( $\star$ , check.names = !optional). See

also the make.names argument of the matrix method.

stringsAsFactors

logical: should the character vector be converted to a factor?

#### Value

as.data.frame.Matrix: A data frame representation of the S4 Matrix

#### See Also

SeuratObject::as.sparse

Assay-class The Assay Class

#### **Description**

The Assay object is the basic unit of Seurat; for more details, please see the documentation in SeuratObject

#### See Also

SeuratObject::Assay-class

AugmentPlot

Augments ggplot2-based plot with a PNG image.

### Description

Creates "vector-friendly" plots. Does this by saving a copy of the plot as a PNG file, then adding the PNG image with annotation\_raster to a blank plot of the same dimensions as plot. Please note: original legends and axes will be lost during augmentation.

#### Usage

```
AugmentPlot(plot, width = 10, height = 10, dpi = 100)
```

18 AutoPointSize

#### **Arguments**

plot A ggplot object

width, height Width and height of PNG version of plot

dpi Plot resolution

#### Value

A ggplot object

# **Examples**

```
## Not run:
data("pbmc_small")
plot <- DimPlot(object = pbmc_small)
AugmentPlot(plot = plot)
## End(Not run)</pre>
```

AutoPointSize

Automagically calculate a point size for ggplot2-based scatter plots

# Description

It happens to look good

#### Usage

```
AutoPointSize(data, raster = NULL)
```

### **Arguments**

data A data frame being passed to ggplot2

raster If TRUE, point size is set to 1

### Value

The "optimal" point size for visualizing these data

```
df \leftarrow data.frame(x = rnorm(n = 10000), y = runif(n = 10000))
AutoPointSize(data = df)
```

AverageExpression 19

AverageExpression

Averaged feature expression by identity class

#### **Description**

Returns averaged expression values for each identity class

### Usage

```
AverageExpression(
  object,
  assays = NULL,
  features = NULL,
  return.seurat = FALSE,
  group.by = "ident",
  add.ident = NULL,
  slot = "data",
  verbose = TRUE,
  ...
)
```

#### **Arguments**

| ect Seurat object | t   |
|-------------------|-----|
| ect Seurat of     | mec |

assays Which assays to use. Default is all assays

features Features to analyze. Default is all features in the assay

return. seurat Whether to return the data as a Seurat object. Default is FALSE

group.by Categories for grouping (e.g, ident, replicate, celltype); 'ident' by default

add.ident (Deprecated) Place an additional label on each cell prior to pseudobulking (very

useful if you want to observe cluster pseudobulk values, separated by replicate,

for example)

slot Slot(s) to use; if multiple slots are given, assumed to follow the order of 'assays'

(if specified) or object's assays

verbose Print messages and show progress bar

... Arguments to be passed to methods such as CreateSeuratObject

#### **Details**

If slot is set to 'data', this function assumes that the data has been log normalized and therefore feature values are exponentiated prior to averaging so that averaging is done in non-log space. Otherwise, if slot is set to either 'counts' or 'scale.data', no exponentiation is performed prior to averaging If return.seurat = TRUE and slot is not 'scale.data', averaged values are placed in the 'counts' slot of the returned object and the log of averaged values are placed in the 'data' slot. ScaleData is then run on the default assay before returning the object. If return.seurat = TRUE and slot is 'scale.data', the 'counts' slot is left empty, the 'data' slot is filled with NA, and 'scale.data' is set to the aggregated values.

20 BarcodeInflectionsPlot

#### Value

Returns a matrix with genes as rows, identity classes as columns. If return.seurat is TRUE, returns an object of class Seurat.

### **Examples**

```
data("pbmc_small")
head(AverageExpression(object = pbmc_small))
```

BarcodeInflectionsPlot

Plot the Barcode Distribution and Calculated Inflection Points

### **Description**

This function plots the calculated inflection points derived from the barcode-rank distribution.

#### Usage

```
BarcodeInflectionsPlot(object)
```

#### **Arguments**

object

Seurat object

#### **Details**

See [CalculateBarcodeInflections()] to calculate inflection points and [SubsetByBarcodeInflections()] to subsequently subset the Seurat object.

### Value

Returns a 'ggplot2' object showing the by-group inflection points and provided (or default) rank threshold values in grey.

#### Author(s)

Robert A. Amezquita, <robert.amezquita@fredhutch.org>

BarcodeInflectionsPlot(pbmc_small)</pre>
```

BGTextColor 21

| BGTextColor | Determine text color based on background color |
|-------------|------------------------------------------------|
|             | Ţ.                                             |

# Description

Determine text color based on background color

# Usage

```
BGTextColor(
  background,
  threshold = 186,
  w3c = FALSE,
  dark = "black",
  light = "white"
)
```

# Arguments

| background | A vector of background colors; supports R color names and hexadecimal codes                                  |
|------------|--------------------------------------------------------------------------------------------------------------|
| threshold  | Intensity threshold for light/dark cutoff; intensities greater than the shold yield dark, others yield light |
| w3c        | Use W3C formula for calculating background text color; ignores threshold                                     |
| dark       | Color for dark text                                                                                          |
| light      | Color for light text                                                                                         |

### Value

A named vector of either dark or light, depending on background; names of vector are background

```
BGTextColor(background = c('black', 'white', '#E76BF3'))
```

22 BlackAndWhite

| BlackAndWhite |
|---------------|
|---------------|

Create a custom color palette

# Description

Creates a custom color palette based on low, middle, and high color values

#### Usage

```
BlackAndWhite(mid = NULL, k = 50)
BlueAndRed(k = 50)
CustomPalette(low = "white", high = "red", mid = NULL, k = 50)
PurpleAndYellow(k = 50)
```

### Arguments

mid middle color. Optional.

k number of steps (colors levels) to include between low and high values

low color high high color

#### Value

A color palette for plotting

```
df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
plot(df, col = BlackAndWhite())

df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
plot(df, col = BlueAndRed())

myPalette <- CustomPalette()
myPalette

df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
plot(df, col = PurpleAndYellow())</pre>
```

BuildClusterTree 23

| BuildClusterTree | Phylogenetic Analysis of Identity Classes |  |
|------------------|-------------------------------------------|--|
|------------------|-------------------------------------------|--|

# Description

Constructs a phylogenetic tree relating the 'average' cell from each identity class. Tree is estimated based on a distance matrix constructed in either gene expression space or PCA space.

# Usage

```
BuildClusterTree(
  object,
  assay = NULL,
  features = NULL,
  dims = NULL,
  reduction = "pca",
  graph = NULL,
  slot = "data",
  reorder = FALSE,
  reorder.numeric = FALSE,
  verbose = TRUE
)
```

### **Arguments**

| object          | Seurat object                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assay           | Assay to use for the analysis.                                                                                                                                                     |
| features        | Genes to use for the analysis. Default is the set of variable genes (VariableFeatures(object = object))                                                                            |
| dims            | If set, tree is calculated in dimension reduction space; overrides features                                                                                                        |
| reduction       | Name of dimension reduction to use. Only used if dims is not NULL.                                                                                                                 |
| graph           | If graph is passed, build tree based on graph connectivity between clusters; over-<br>rides dims and features                                                                      |
| slot            | Slot(s) to use; if multiple slots are given, assumed to follow the order of 'assays' (if specified) or object's assays                                                             |
| reorder         | Re-order identity classes (factor ordering), according to position on the tree. This groups similar classes together which can be helpful, for example, when drawing violin plots. |
| reorder.numeric |                                                                                                                                                                                    |
|                 | Re-order identity classes according to position on the tree, assigning a numeric value ('1' is the leftmost node)                                                                  |
| verbose         | Show progress updates                                                                                                                                                              |

24 CalcPerturbSig

#### **Details**

Note that the tree is calculated for an 'average' cell, so gene expression or PC scores are averaged across all cells in an identity class before the tree is constructed.

#### Value

A Seurat object where the cluster tree can be accessed with Tool

### **Examples**

```
if (requireNamespace("ape", quietly = TRUE)) {
   data("pbmc_small")
   pbmc_small
   pbmc_small <- BuildClusterTree(object = pbmc_small)
   Tool(object = pbmc_small, slot = 'BuildClusterTree')
}</pre>
```

CalcPerturbSig

Calculate a perturbation Signature

### **Description**

Function to calculate perturbation signature for pooled CRISPR screen datasets. For each target cell (expressing one target gRNA), we identified 20 cells from the control pool (non-targeting cells) with the most similar mRNA expression profiles. The perturbation signature is calculated by subtracting the averaged mRNA expression profile of the non-targeting neighbors from the mRNA expression profile of the target cell.

#### Usage

```
CalcPerturbSig(
  object,
  assay = NULL,
  features = NULL,
  slot = "data",
  gd.class = "guide_ID",
  nt.cell.class = "NT",
  split.by = NULL,
  num.neighbors = NULL,
  reduction = "pca",
  ndims = 15,
  new.assay.name = "PRTB",
  verbose = TRUE
)
```

CalculateBarcodeInflections 25

#### **Arguments**

object An object of class Seurat. Name of Assay PRTB signature is being calculated on. assay Features to compute PRTB signature for. Defaults to the variable features set in features the assay specified. slot Data slot to use for PRTB signature calculation. Metadata column containing target gene classification. gd.class nt.cell.class Non-targeting gRNA cell classification identity. Provide metadata column if multiple biological replicates exist to calculate PRTB split.by signature for every replicate separately. num.neighbors Number of nearest neighbors to consider. reduction Reduction method used to calculate nearest neighbors. ndims Number of dimensions to use from dimensionality reduction method. new.assay.name Name for the new assay.

#### Value

verbose

Returns a Seurat object with a new assay added containing the perturbation signature for all cells in the data slot.

CalculateBarcodeInflections

Calculate the Barcode Distribution Inflection

# Description

This function calculates an adaptive inflection point ("knee") of the barcode distribution for each sample group. This is useful for determining a threshold for removing low-quality samples.

#### Usage

```
CalculateBarcodeInflections(
  object,
  barcode.column = "nCount_RNA",
  group.column = "orig.ident",
  threshold.low = NULL,
  threshold.high = NULL
)
```

#### **Arguments**

object Seurat object
barcode.column Column to use as proxy for barcodes ("nCount\_RNA" by default)
group.column Column to group by ("orig.ident" by default)
threshold.low Ignore barcodes of rank below this threshold in inflection calculation

threshold.high Ignore barcodes of rank above thisf threshold in inflection calculation

#### **Details**

The function operates by calculating the slope of the barcode number vs. rank distribution, and then finding the point at which the distribution changes most steeply (the "knee"). Of note, this calculation often must be restricted as to the range at which it performs, so 'threshold' parameters are provided to restrict the range of the calculation based on the rank of the barcodes. [BarcodeInflectionsPlot()] is provided as a convenience function to visualize and test different thresholds and thus provide more sensical end results.

See [BarcodeInflectionsPlot()] to visualize the calculated inflection points and [SubsetByBarcodeInflections()] to subsequently subset the Seurat object.

#### Value

Returns Seurat object with a new list in the 'tools' slot, 'CalculateBarcodeInflections' with values:

\* 'barcode\_distribution' - contains the full barcode distribution across the entire dataset \* 'inflection\_points' - the calculated inflection points within the thresholds \* 'threshold\_values' - the provided (or default) threshold values to search within for inflections \* 'cells\_pass' - the cells that pass the inflection point calculation

#### Author(s)

Robert A. Amezquita, <robert.amezquita@fredhutch.org>

CalculateBarcodeInflections(pbmc_small, group.column = 'groups')
```

CaseMatch 27

CaseMatch

Match the case of character vectors

### **Description**

Match the case of character vectors

### Usage

```
CaseMatch(search, match)
```

### **Arguments**

search A vector of search terms

match A vector of characters whose case should be matched

### Value

Values from search present in match with the case of match

# **Examples**

```
data("pbmc_small")
cd_genes <- c('Cd79b', 'Cd19', 'Cd200')
CaseMatch(search = cd_genes, match = rownames(x = pbmc_small))</pre>
```

cc.genes

Cell cycle genes

# Description

A list of genes used in cell-cycle regression

### Usage

```
cc.genes
```

#### **Format**

A list of two vectors

```
s.genes Genes associated with S-phase g2m.genes Genes associated with G2M-phase
```

#### **Source**

```
https://www.science.org/doi/abs/10.1126/science.aad0501
```

```
cc.genes.updated.2019 Cell cycle genes: 2019 update
```

### **Description**

A list of genes used in cell-cycle regression, updated with 2019 symbols

### Usage

```
cc.genes.updated.2019
```

#### **Format**

```
A list of two vectors
```

```
s.genes Genes associated with S-phaseg2m.genes Genes associated with G2M-phase
```

# **Updated symbols**

The following symbols were updated from cc.genes

```
s.genes • MCM2: MCM7
• MLF1IP: CENPU
• RPA2: POLR1B
• BRIP1: MRPL36

g2m.genes • FAM64A: PIMREG
• HN1: JPT1
```

## End(Not run)</pre>
```

CellCycleScoring 29

CellCycleScoring

Score cell cycle phases

### **Description**

Score cell cycle phases

### Usage

```
CellCycleScoring(
  object,
  s.features,
  g2m.features,
  ctrl = NULL,
  set.ident = FALSE,
  ...
)
```

### Arguments

object A Seurat object

s.features A vector of features associated with S phase

g2m.features A vector of features associated with G2M phase

ctrl Number of control features selected from the same bin per analyzed feature supplied to AddModuleScore. Defaults to value equivalent to minimum number of features present in 's.features' and 'g2m.features'.

set.ident If true, sets identity to phase assignments Stashes old identities in 'old.ident'

Arguments to be passed to AddModuleScore

#### Value

A Seurat object with the following columns added to object meta data: S.Score, G2M.Score, and Phase

#### See Also

AddModuleScore

```
## Not run:
data("pbmc_small")
# pbmc_small doesn't have any cell-cycle genes
# To run CellCycleScoring, please use a dataset with cell-cycle genes
# An example is available at http://satijalab.org/seurat/cell_cycle_vignette.html
pbmc_small <- CellCycleScoring(
   object = pbmc_small,</pre>
```

30 Cells.SCTModel

```
g2m.features = cc.genes$g2m.genes,
    s.features = cc.genes$s.genes
)
head(x = pbmc_small@meta.data)
## End(Not run)
```

Cells.SCTModel

Get Cell Names

# Description

Get Cell Names

### Usage

```
## S3 method for class 'SCTModel'
Cells(x, ...)

## S3 method for class 'SlideSeq'
Cells(x, ...)

## S3 method for class 'STARmap'
Cells(x, ...)

## S3 method for class 'VisiumV1'
Cells(x, ...)
```

### **Arguments**

x An object

... Arguments passed to other methods

### See Also

SeuratObject::Cells

CellsByImage 31

| CellsByImage | Get a vector of cell names associated with an image (or set of images) |
|--------------|------------------------------------------------------------------------|
|              |                                                                        |

### **Description**

Get a vector of cell names associated with an image (or set of images)

# Usage

```
CellsByImage(object, images = NULL, unlist = FALSE)
```

# Arguments

object Seurat object

images Vector of image names

unlist Return as a single vector of cell names as opposed to a list, named by image

name.

### Value

A vector of cell names

# **Examples**

```
## Not run:
CellsByImage(object = object, images = "slice1")
## End(Not run)
```

CellScatter

Cell-cell scatter plot

# Description

Creates a plot of scatter plot of features across two single cells. Pearson correlation between the two cells is displayed above the plot.

CellScatter CellScatter

# Usage

```
CellScatter(
  object,
  cell1,
  cell2,
  features = NULL,
  highlight = NULL,
  cols = NULL,
  pt.size = 1,
  smooth = FALSE,
  raster = NULL,
  raster.dpi = c(512, 512)
)
```

# Arguments

| object     | Seurat object                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| cell1      | Cell 1 name                                                                                                                                  |
| cell2      | Cell 2 name                                                                                                                                  |
| features   | Features to plot (default, all features)                                                                                                     |
| highlight  | Features to highlight                                                                                                                        |
| cols       | Colors to use for identity class plotting.                                                                                                   |
| pt.size    | Size of the points on the plot                                                                                                               |
| smooth     | Smooth the graph (similar to smoothScatter)                                                                                                  |
| raster     | Convert points to raster format, default is NULL which will automatically use raster if the number of points plotted is greater than 100,000 |
| raster.dpi | Pixel resolution for rasterized plots, passed to geom_scattermore(). Default is $c(512,512)$ .                                               |

### Value

A ggplot object

```
data("pbmc_small")
CellScatter(object = pbmc_small, cell1 = 'ATAGGAGAAACAGA', cell2 = 'CATCAGGATGCACA')
```

CellSelector 33

|--|

# Description

Select points on a scatterplot and get information about them

# Usage

```
CellSelector(plot, object = NULL, ident = "SelectedCells", ...)
FeatureLocator(plot, ...)
```

### **Arguments**

| plot   | A ggplot2 plot                                                                                                 |
|--------|----------------------------------------------------------------------------------------------------------------|
| object | An optional Seurat object; if passes, will return an object with the identities of selected cells set to ident |
| ident  | An optional new identity class to assign the selected cells                                                    |
|        | Ignored                                                                                                        |

#### Value

If object is NULL, the names of the points selected; otherwise, a Seurat object with the selected cells identity classes set to ident

### See Also

```
DimPlot FeaturePlot
```

```
## Not run:
data("pbmc_small")
plot <- DimPlot(object = pbmc_small)
# Follow instructions in the terminal to select points
cells.located <- CellSelector(plot = plot)
cells.located
# Automatically set the identity class of selected cells and return a new Seurat object
pbmc_small <- CellSelector(plot = plot, object = pbmc_small, ident = 'SelectedCells')
## End(Not run)</pre>
```

CollapseEmbeddingOutliers

Move outliers towards center on dimension reduction plot

#### **Description**

Move outliers towards center on dimension reduction plot

### Usage

```
CollapseEmbeddingOutliers(
  object,
  reduction = "umap",
  dims = 1:2,
  group.by = "ident",
  outlier.sd = 2,
  reduction.key = "UMAP_"
)
```

### **Arguments**

```
object Seurat object
reduction Name of DimReduc to adjust
dims Dimensions to visualize
group.by Group (color) cells in different ways (for example, orig.ident)
outlier.sd Controls the outlier distance
reduction.key Key for DimReduc that is returned
```

### Value

Returns a DimReduc object with the modified embeddings

```
## Not run:
data("pbmc_small")
pbmc_small <- FindClusters(pbmc_small, resolution = 1.1)
pbmc_small <- RunUMAP(pbmc_small, dims = 1:5)
DimPlot(pbmc_small, reduction = "umap")
pbmc_small[["umap_new"]] <- CollapseEmbeddingOutliers(pbmc_small, reduction = "umap", reduction.key = 'umap_', outlier.sd = 0.5)
DimPlot(pbmc_small, reduction = "umap_new")
## End(Not run)</pre>
```

```
CollapseSpeciesExpressionMatrix
```

Slim down a multi-species expression matrix, when only one species is primarily of interenst.

# Description

Valuable for CITE-seq analyses, where we typically spike in rare populations of 'negative control' cells from a different species.

### Usage

```
CollapseSpeciesExpressionMatrix(
  object,
  prefix = "HUMAN_",
  controls = "MOUSE_",
  ncontrols = 100
)
```

### Arguments

| object    | A UMI count matrix. Should contain rownames that start with the ensuing arguments prefix.1 or prefix.2                                                                            |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefix    | The prefix denoting rownames for the species of interest. Default is "HU-MAN_". These rownames will have this prefix removed in the returned matrix.                              |
| controls  | The prefix denoting rownames for the species of 'negative control' cells. Default is "MOUSE_".                                                                                    |
| ncontrols | How many of the most highly expressed (average) negative control features (by default, 100 mouse genes), should be kept? All other rownames starting with prefix.2 are discarded. |

#### Value

A UMI count matrix. Rownames that started with prefix have this prefix discarded. For rownames starting with controls, only the ncontrols most highly expressed features are kept, and the prefix is kept. All other rows are retained.

```
## Not run:
cbmc.rna.collapsed <- CollapseSpeciesExpressionMatrix(cbmc.rna)
## End(Not run)</pre>
```

36 ColorDimSplit

ColorDimSplit

Color dimensional reduction plot by tree split

#### **Description**

Returns a DimPlot colored based on whether the cells fall in clusters to the left or to the right of a node split in the cluster tree.

### Usage

```
ColorDimSplit(
  object,
  node,
  left.color = "red",
  right.color = "blue",
  other.color = "grey50",
  ...
)
```

#### **Arguments**

object Seurat object

node Node in cluster tree on which to base the split

left.color Color for the left side of the split right.color Color for the right side of the split

other.color Color for all other cells

... Arguments passed on to DimPlot

dims Dimensions to plot, must be a two-length numeric vector specifying xand y-dimensions

cells Vector of cells to plot (default is all cells)

cols Vector of colors, each color corresponds to an identity class. This may also be a single character or numeric value corresponding to a palette as specified by brewer.pal.info. By default, ggplot2 assigns colors. We also include a number of palettes from the pals package. See DiscretePalette for details.

pt.size Adjust point size for plotting

reduction Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca

group.by Name of one or more metadata columns to group (color) cells by (for example, orig.ident); pass 'ident' to group by identity class

split.by Name of a metadata column to split plot by; see FetchData for more details

shape.by If NULL, all points are circles (default). You can specify any cell attribute (that can be pulled with FetchData) allowing for both different colors and different shapes on cells. Only applicable if raster = FALSE.

ColorDimSplit 37

order Specify the order of plotting for the idents. This can be useful for crowded plots if points of interest are being buried. Provide either a full list of valid idents or a subset to be plotted last (on top)

shuffle Whether to randomly shuffle the order of points. This can be useful for crowded plots if points of interest are being buried. (default is FALSE)

seed Sets the seed if randomly shuffling the order of points.

label Whether to label the clusters

label.size Sets size of labels

label.color Sets the color of the label text

label.box Whether to put a box around the label text (geom\_text vs geom\_label) repel Repel labels

cells.highlight A list of character or numeric vectors of cells to highlight. If only one group of cells desired, can simply pass a vector instead of a list. If set, colors selected cells to the color(s) in cols.highlight and other cells black (white if dark.theme = TRUE); will also resize to the size(s) passed to sizes.highlight

cols.highlight A vector of colors to highlight the cells as; will repeat to the length groups in cells.highlight

sizes.highlight Size of highlighted cells; will repeat to the length groups in cells.highlight

na. value Color value for NA points when using custom scale

ncol Number of columns for display when combining plots

combine Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects

raster Convert points to raster format, default is NULL which automatically rasterizes if plotting more than 100,000 cells

raster.dpi Pixel resolution for rasterized plots, passed to geom\_scattermore(). Default is c(512, 512).

#### Value

Returns a DimPlot

## See Also

DimPlot

#### **Examples**

```
if (requireNamespace("ape", quietly = TRUE)) {
   data("pbmc_small")
   pbmc_small <- BuildClusterTree(object = pbmc_small, verbose = FALSE)
   PlotClusterTree(pbmc_small)
   ColorDimSplit(pbmc_small, node = 5)
}</pre>
```

38 CombinePlots

CombinePlots

Combine ggplot2-based plots into a single plot

## **Description**

Combine ggplot2-based plots into a single plot

#### Usage

```
CombinePlots(plots, ncol = NULL, legend = NULL, ...)
```

## Arguments

plots A list of gg objects

ncol Number of columns

legend Combine legends into a single legend choose from 'right' or 'bottom'; pass 'none' to remove legends, or NULL to leave legends as they are

... Extra parameters passed to plot\_grid

#### Value

A combined plot

### **Examples**

```
data("pbmc_small")
pbmc_small[['group']] <- sample(</pre>
  x = c('g1', 'g2'),

contrast-theory

Get the intensity and/or luminance of a color

## Description

Get the intensity and/or luminance of a color

## Usage

```
Intensity(color)
Luminance(color)
```

## **Arguments**

color

A vector of colors

## Value

A vector of intensities/luminances for each color

#### **Source**

https://stackoverflow.com/questions/3942878/how-to-decide-font-color-in-white-or-black-depending-o

# **Examples**

```
Intensity(color = c('black', 'white', '#E76BF3'))
Luminance(color = c('black', 'white', '#E76BF3'))
```

 ${\tt Create SCTAssay Object} \quad \textit{Create a SCTAssay object}$ 

## Description

Create a SCT object from a feature (e.g. gene) expression matrix and a list of SCTModels. The expected format of the input matrix is features x cells.

40 CustomDistance

### Usage

```
CreateSCTAssayObject(
  counts,
  data,
  scale.data = NULL,
  umi.assay = "RNA",
  min.cells = 0,
  min.features = 0,
  SCTModel.list = NULL
)
```

## **Arguments**

counts Unnormalized data such as raw counts or TPMs

Prenormalized data; if provided, do not pass counts

scale.data a residual matrix

umi.assay The UMI assay name. Default is RNA

min.cells Include features detected in at least this many cells. Will subset the counts matrix as well. To reintroduce excluded features, create a new object with a lower cutoff.

min.features Include cells where at least this many features are detected.

SCTModel.list list of SCTModels

## **Details**

Non-unique cell or feature names are not allowed. Please make unique before calling this function.

CustomDistance Run a custom distance function on an input data matrix

## Description

Run a custom distance function on an input data matrix

## Usage

```
CustomDistance(my.mat, my.function, ...)
```

#### **Arguments**

my.mat A matrix to calculate distance on my.function A function to calculate distance Extra parameters to my.function

DEenrichRPlot 41

## Value

A distance matrix

## Author(s)

Jean Fan

## **Examples**

```
data("pbmc_small")
# Define custom distance matrix
manhattan.distance <- function(x, y) return(sum(abs(x-y)))
input.data <- GetAssayData(pbmc_small, assay.type = "RNA", slot = "scale.data")
cell.manhattan.dist <- CustomDistance(input.data, manhattan.distance)</pre>
```

 ${\tt DEenrichRPlot}$ 

DE and EnrichR pathway visualization barplot

### **Description**

DE and EnrichR pathway visualization barplot

## Usage

```
DEenrichRPlot(
  object,
  ident.1 = NULL,
  ident.2 = NULL,
  balanced = TRUE,
  logfc.threshold = 0.25,
  assay = NULL,
  max.genes,
  test.use = "wilcox",
  p.val.cutoff = 0.05,
  cols = NULL,
  enrich.database = NULL,
  num.pathway = 10,
  return.gene.list = FALSE,
  ...
)
```

42 DEenrichRPlot

#### **Arguments**

object Name of object class Seurat.

ident.1 Cell class identity 1. ident.2 Cell class identity 2.

balanced Option to display pathway enrichments for both negative and positive DE genes.If

false, only positive DE gene will be displayed.

logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

assay Assay to use in differential expression testing

max.genes Maximum number of genes to use as input to enrichR.

test.use Denotes which test to use. Available options are:

- "wilcox" : Identifies differentially expressed genes between two groups of cells using a Wilcoxon Rank Sum test (default)
- "bimod": Likelihood-ratio test for single cell gene expression, (McDavid et al., Bioinformatics, 2013)
- "roc": Identifies 'markers' of gene expression using ROC analysis. For each gene, evaluates (using AUC) a classifier built on that gene alone, to classify between two groups of cells. An AUC value of 1 means that expression values for this gene alone can perfectly classify the two groupings (i.e. Each of the cells in cells.1 exhibit a higher level than each of the cells in cells.2). An AUC value of 0 also means there is perfect classification, but in the other direction. A value of 0.5 implies that the gene has no predictive power to classify the two groups. Returns a 'predictive power' (abs(AUC-0.5) \* 2) ranked matrix of putative differentially expressed genes.
- "t": Identify differentially expressed genes between two groups of cells using the Student's t-test.
- "negbinom": Identifies differentially expressed genes between two groups of cells using a negative binomial generalized linear model. Use only for UMI-based datasets
- "poisson": Identifies differentially expressed genes between two groups of cells using a poisson generalized linear model. Use only for UMI-based datasets
- "LR": Uses a logistic regression framework to determine differentially expressed genes. Constructs a logistic regression model predicting group membership based on each feature individually and compares this to a null model with a likelihood ratio test.
- "MAST": Identifies differentially expressed genes between two groups of cells using a hurdle model tailored to scRNA-seq data. Utilizes the MAST package to run the DE testing.
- "DESeq2": Identifies differentially expressed genes between two groups of cells based on a model using DESeq2 which uses a negative binomial distribution (Love et al, Genome Biology, 2014). This test does not support pre-

DietSeurat 43

filtering of genes based on average difference (or percent detection rate) between cell groups. However, genes may be pre-filtered based on their minimum detection rate (min.pct) across both cell groups. To use this method,

please install DESeq2, using the instructions at https://bioconductor.org/packages/release/bioc/html/I

p.val.cutoff Cutoff to select DE genes.

cols A list of colors to use for barplots.

enrich.database

Database to use from enrichR.

num. pathway Number of pathways to display in barplot.

return.gene.list

Return list of DE genes

... Arguments passed to other methods and to specific DE methods

#### Value

Returns one (only enriched) or two (both enriched and depleted) barplots with the top enriched/depleted GO terms from EnrichR.

DietSeurat

Slim down a Seurat object

## **Description**

Keep only certain aspects of the Seurat object. Can be useful in functions that utilize merge as it reduces the amount of data in the merge.

#### Usage

```
DietSeurat(
  object,
  counts = TRUE,
  data = TRUE,
  scale.data = FALSE,
  features = NULL,
  assays = NULL,
  dimreducs = NULL,
  graphs = NULL,
  misc = TRUE
)
```

## **Arguments**

object Seurat object

counts Preserve the count matrices for the assays specified

data Preserve the data slot for the assays specified

DimHeatmap

| scale.data | Preserve the scale.data slot for the assays specified                          |
|------------|--------------------------------------------------------------------------------|
| features   | Only keep a subset of features, defaults to all features                       |
| assays     | Only keep a subset of assays specified here                                    |
| dimreducs  | Only keep a subset of DimReducs specified here (if NULL, remove all DimReducs) |
| graphs     | Only keep a subset of Graphs specified here (if NULL, remove all Graphs)       |
| misc       | Preserve the misc slot; default is TRUE                                        |
|            |                                                                                |

DimHeatmap

Dimensional reduction heatmap

## Description

Draws a heatmap focusing on a principal component. Both cells and genes are sorted by their principal component scores. Allows for nice visualization of sources of heterogeneity in the dataset.

## Usage

```
DimHeatmap(
  object,
  dims = 1,
  nfeatures = 30,
  cells = NULL,
  reduction = "pca",
  disp.min = -2.5,
  disp.max = NULL,
  balanced = TRUE,
  projected = FALSE,
 ncol = NULL,
  fast = TRUE,
  raster = TRUE,
  slot = "scale.data",
  assays = NULL,
  combine = TRUE
)
PCHeatmap(object, ...)
```

## Arguments

object Seurat object

dims Dimensions to plot

nfeatures Number of genes to plot

cells A list of cells to plot. If numeric, just plots the top cells.

DimPlot 45

| reduction | Which dimensional reduction to use                                                                                                                                                                                                                                            |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disp.min  | Minimum display value (all values below are clipped)                                                                                                                                                                                                                          |
| disp.max  | Maximum display value (all values above are clipped); defaults to 2.5 if slot is 'scale.data', $6$ otherwise                                                                                                                                                                  |
| balanced  | Plot an equal number of genes with both + and - scores.                                                                                                                                                                                                                       |
| projected | Use the full projected dimensional reduction                                                                                                                                                                                                                                  |
| ncol      | Number of columns to plot                                                                                                                                                                                                                                                     |
| fast      | If true, use image to generate plots; faster than using ggplot2, but not customizable                                                                                                                                                                                         |
| raster    | If true, plot with geom_raster, else use geom_tile. geom_raster may look blurry on some viewing applications such as Preview due to how the raster is interpolated. Set this to FALSE if you are encountering that issue (note that plots may take longer to produce/render). |
| slot      | Data slot to use, choose from 'raw.data', 'data', or 'scale.data'                                                                                                                                                                                                             |
| assays    | A vector of assays to pull data from                                                                                                                                                                                                                                          |
| combine   | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects                                                                                                                                                                              |
| • • •     | Extra parameters passed to DimHeatmap                                                                                                                                                                                                                                         |
|           |                                                                                                                                                                                                                                                                               |

#### Value

No return value by default. If using fast = FALSE, will return a patchworked ggplot object if combine = TRUE, otherwise returns a list of ggplot objects

| ot Dimensional reduction plot |
|-------------------------------|
|-------------------------------|

## Description

Graphs the output of a dimensional reduction technique on a 2D scatter plot where each point is a cell and it's positioned based on the cell embeddings determined by the reduction technique. By default, cells are colored by their identity class (can be changed with the group.by parameter).

46 DimPlot

## Usage

```
DimPlot(
  object,
  dims = c(1, 2),
  cells = NULL,
  cols = NULL,
  pt.size = NULL,
  reduction = NULL,
  group.by = NULL,
  split.by = NULL,
  shape.by = NULL,
  order = NULL,
  shuffle = FALSE,
  seed = 1,
  label = FALSE,
  label.size = 4,
  label.color = "black",
  label.box = FALSE,
  repel = FALSE,
  cells.highlight = NULL,
  cols.highlight = "#DE2D26",
  sizes.highlight = 1,
  na.value = "grey50",
  ncol = NULL,
  combine = TRUE,
  raster = NULL,
  raster.dpi = c(512, 512)
)
PCAPlot(object, ...)
TSNEPlot(object, ...)
UMAPPlot(object, ...)
```

# Arguments

| object  | Seurat object                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dims    | Dimensions to plot, must be a two-length numeric vector specifying x- and y-dimensions                                                                                                                                                                                                                           |
| cells   | Vector of cells to plot (default is all cells)                                                                                                                                                                                                                                                                   |
| cols    | Vector of colors, each color corresponds to an identity class. This may also be a single character or numeric value corresponding to a palette as specified by brewer.pal.info. By default, ggplot2 assigns colors. We also include a number of palettes from the pals package. See DiscretePalette for details. |
| pt.size | Adjust point size for plotting                                                                                                                                                                                                                                                                                   |

DimPlot 47

| reduction       | Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| group.by        | Name of one or more metadata columns to group (color) cells by (for example, orig.ident); pass 'ident' to group by identity class                                                                                                                                                                                           |
| split.by        | Name of a metadata column to split plot by; see FetchData for more details                                                                                                                                                                                                                                                  |
| shape.by        | If NULL, all points are circles (default). You can specify any cell attribute (that can be pulled with FetchData) allowing for both different colors and different shapes on cells. Only applicable if raster = FALSE.                                                                                                      |
| order           | Specify the order of plotting for the idents. This can be useful for crowded plots if points of interest are being buried. Provide either a full list of valid idents or a subset to be plotted last (on top)                                                                                                               |
| shuffle         | Whether to randomly shuffle the order of points. This can be useful for crowded plots if points of interest are being buried. (default is FALSE)                                                                                                                                                                            |
| seed            | Sets the seed if randomly shuffling the order of points.                                                                                                                                                                                                                                                                    |
| label           | Whether to label the clusters                                                                                                                                                                                                                                                                                               |
| label.size      | Sets size of labels                                                                                                                                                                                                                                                                                                         |
| label.color     | Sets the color of the label text                                                                                                                                                                                                                                                                                            |
| label.box       | Whether to put a box around the label text (geom_text vs geom_label)                                                                                                                                                                                                                                                        |
| repel           | Repel labels                                                                                                                                                                                                                                                                                                                |
| cells.highlight |                                                                                                                                                                                                                                                                                                                             |
|                 | A list of character or numeric vectors of cells to highlight. If only one group of cells desired, can simply pass a vector instead of a list. If set, colors selected cells to the color(s) in cols.highlight and other cells black (white if dark.theme = TRUE); will also resize to the size(s) passed to sizes.highlight |
| cols.highlight  | A vector of colors to highlight the cells as; will repeat to the length groups in cells.highlight                                                                                                                                                                                                                           |
| sizes.highlight |                                                                                                                                                                                                                                                                                                                             |
|                 | Size of highlighted cells; will repeat to the length groups in cells.highlight                                                                                                                                                                                                                                              |
| na.value        | Color value for NA points when using custom scale                                                                                                                                                                                                                                                                           |
| ncol            | Number of columns for display when combining plots                                                                                                                                                                                                                                                                          |
| combine         | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects                                                                                                                                                                                                                            |
| raster          | Convert points to raster format, default is NULL which automatically rasterizes if plotting more than $100,\!000$ cells                                                                                                                                                                                                     |
| raster.dpi      | Pixel resolution for rasterized plots, passed to geom_scattermore(). Default is $c(512,512)$ .                                                                                                                                                                                                                              |
|                 | Extra parameters passed to DimPlot                                                                                                                                                                                                                                                                                          |
|                 |                                                                                                                                                                                                                                                                                                                             |

## Value

A patchworked ggplot object if combine = TRUE; otherwise, a list of ggplot objects

48 DiscretePalette

## Note

For the old do.hover and do.identify functionality, please see HoverLocator and CellSelector, respectively.

#### See Also

FeaturePlot HoverLocator CellSelector FetchData

## **Examples**

```
data("pbmc_small")
DimPlot(object = pbmc_small)
DimPlot(object = pbmc_small, split.by = 'ident')
```

DimReduc-class

The DimReduc Class

## Description

The DimReduc object stores a dimensionality reduction taken out in Seurat; for more details, please see the documentation in SeuratObject

## See Also

```
SeuratObject::DimReduc-class
```

DiscretePalette

Discrete colour palettes from pals

#### **Description**

These are included here because pals depends on a number of compiled packages, and this can lead to increases in run time for Travis, and generally should be avoided when possible.

## Usage

```
DiscretePalette(n, palette = NULL, shuffle = FALSE)
```

#### **Arguments**

| n       | Number of colours to be generated.                                                                                                                                |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| palette | Options are "alphabet", "alphabet2", "glasbey", "polychrome", "stepped", and "parade". Can be omitted and the function will use the one based on the requested n. |
| shuffle | Shuffle the colors in the selected palette.                                                                                                                       |

DoHeatmap 49

#### **Details**

These palettes are a much better default for data with many classes than the default ggplot2 palette. Many thanks to Kevin Wright for writing the pals package.

Taken from the pals package (Licence: GPL-3). https://cran.r-project.org/package=pals Credit: Kevin Wright

#### Value

A vector of colors

DoHeatmap

Feature expression heatmap

## **Description**

Draws a heatmap of single cell feature expression.

## Usage

```
DoHeatmap(
  object,
  features = NULL,
  cells = NULL,
 group.by = "ident",
  group.bar = TRUE,
  group.colors = NULL,
 disp.min = -2.5,
 disp.max = NULL,
  slot = "scale.data",
 assay = NULL,
 label = TRUE,
  size = 5.5,
 hjust = 0,
  angle = 45,
  raster = TRUE,
  draw.lines = TRUE,
  lines.width = NULL,
 group.bar.height = 0.02,
  combine = TRUE
)
```

## Arguments

object Seurat object

features A vector of features to plot, defaults to VariableFeatures(object = object)

cells A vector of cells to plot

DotPlot

| A vector of variables to group cells by; pass 'ident' to group by cell identity classes                                                                                                                                                                                       |  |  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| Add a color bar showing group status for cells                                                                                                                                                                                                                                |  |  |
| Colors to use for the color bar                                                                                                                                                                                                                                               |  |  |
| Minimum display value (all values below are clipped)                                                                                                                                                                                                                          |  |  |
| Maximum display value (all values above are clipped); defaults to 2.5 if slot is 'scale.data', 6 otherwise                                                                                                                                                                    |  |  |
| Data slot to use, choose from 'raw.data', 'data', or 'scale.data'                                                                                                                                                                                                             |  |  |
| Assay to pull from                                                                                                                                                                                                                                                            |  |  |
| Label the cell identies above the color bar                                                                                                                                                                                                                                   |  |  |
| Size of text above color bar                                                                                                                                                                                                                                                  |  |  |
| Horizontal justification of text above color bar                                                                                                                                                                                                                              |  |  |
| Angle of text above color bar                                                                                                                                                                                                                                                 |  |  |
| If true, plot with geom_raster, else use geom_tile. geom_raster may look blurry on some viewing applications such as Preview due to how the raster is interpolated. Set this to FALSE if you are encountering that issue (note that plots may take longer to produce/render). |  |  |
| Include white lines to separate the groups                                                                                                                                                                                                                                    |  |  |
| Integer number to adjust the width of the separating white lines. Corresponds to the number of "cells" between each group.                                                                                                                                                    |  |  |
| group.bar.height                                                                                                                                                                                                                                                              |  |  |
| Scale the height of the color bar                                                                                                                                                                                                                                             |  |  |
| Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects                                                                                                                                                                              |  |  |
|                                                                                                                                                                                                                                                                               |  |  |

## Value

A patchworked ggplot object if combine = TRUE; otherwise, a list of ggplot objects

## **Examples**

```
data("pbmc_small")
DoHeatmap(object = pbmc_small)
```

| DotPlot | Dot plot visualization |  |
|---------|------------------------|--|
|---------|------------------------|--|

# Description

Intuitive way of visualizing how feature expression changes across different identity classes (clusters). The size of the dot encodes the percentage of cells within a class, while the color encodes the AverageExpression level across all cells within a class (blue is high).

DotPlot 51

# Usage

```
DotPlot(
 object,
 assay = NULL,
 features,
 cols = c("lightgrey", "blue"),
 col.min = -2.5,
 col.max = 2.5,
 dot.min = 0,
 dot.scale = 6,
 idents = NULL,
 group.by = NULL,
 split.by = NULL,
 cluster.idents = FALSE,
  scale = TRUE,
  scale.by = "radius",
 scale.min = NA,
 scale.max = NA
)
```

## **Arguments**

| ٠ | •              |                                                                                                                                                                               |
|---|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|   | object         | Seurat object                                                                                                                                                                 |
|   | assay          | Name of assay to use, defaults to the active assay                                                                                                                            |
|   | features       | Input vector of features, or named list of feature vectors if feature-grouped panels are desired (replicates the functionality of the old $SplitDotPlotGG$ )                  |
|   | cols           | Colors to plot: the name of a palette from RColorBrewer::brewer.pal.info, a pair of colors defining a gradient, or 3+ colors defining multiple gradients (if split.by is set) |
|   | col.min        | Minimum scaled average expression threshold (everything smaller will be set to this)                                                                                          |
|   | col.max        | Maximum scaled average expression threshold (everything larger will be set to this)                                                                                           |
|   | dot.min        | The fraction of cells at which to draw the smallest dot (default is 0). All cell groups with less than this expressing the given gene will have no dot drawn.                 |
|   | dot.scale      | Scale the size of the points, similar to cex                                                                                                                                  |
|   | idents         | Identity classes to include in plot (default is all)                                                                                                                          |
|   | group.by       | Factor to group the cells by                                                                                                                                                  |
|   | split.by       | Factor to split the groups by (replicates the functionality of the old SplitDot-PlotGG); see FetchData for more details                                                       |
|   | cluster.idents | Whether to order identities by hierarchical clusters based on given features, default is FALSE                                                                                |
|   | scale          | Determine whether the data is scaled, TRUE for default                                                                                                                        |
|   | scale.by       | Scale the size of the points by 'size' or by 'radius'                                                                                                                         |
|   | scale.min      | Set lower limit for scaling, use NA for default                                                                                                                               |
|   | scale.max      | Set upper limit for scaling, use NA for default                                                                                                                               |
|   |                |                                                                                                                                                                               |

52 ElbowPlot

## Value

A ggplot object

#### See Also

```
RColorBrewer::brewer.pal.info
```

#### **Examples**

```
data("pbmc_small")
cd_genes <- c("CD247", "CD3E", "CD9")
DotPlot(object = pbmc_small, features = cd_genes)
pbmc_small[['groups']] <- sample(x = c('g1', 'g2'), size = ncol(x = pbmc_small), replace = TRUE)
DotPlot(object = pbmc_small, features = cd_genes, split.by = 'groups')</pre>
```

ElbowPlot

Quickly Pick Relevant Dimensions

## Description

Plots the standard deviations (or approximate singular values if running PCAFast) of the principle components for easy identification of an elbow in the graph. This elbow often corresponds well with the significant dims and is much faster to run than Jackstraw

## Usage

```
ElbowPlot(object, ndims = 20, reduction = "pca")
```

# **Arguments**

object Seurat object

ndims Number of dimensions to plot standard deviation for reduction Reduction technique to plot standard deviation for

#### Value

A ggplot object

### **Examples**

```
data("pbmc_small")
ElbowPlot(object = pbmc_small)
```

ExpMean 53

ExpMean

Calculate the mean of logged values

## **Description**

Calculate mean of logged values in non-log space (return answer in log-space)

## Usage

```
ExpMean(x, ...)
```

## **Arguments**

x A vector of values... Other arguments (not used)

#### Value

Returns the mean in log-space

## **Examples**

```
ExpMean(x = c(1, 2, 3))
```

ExpSD

Calculate the standard deviation of logged values

## Description

Calculate SD of logged values in non-log space (return answer in log-space)

## Usage

```
ExpSD(x)
```

## Arguments

Х

A vector of values

#### Value

Returns the standard deviation in log-space

## **Examples**

```
ExpSD(x = c(1, 2, 3))
```

54 FastRowScale

ExpVar

Calculate the variance of logged values

#### **Description**

Calculate variance of logged values in non-log space (return answer in log-space)

## Usage

```
ExpVar(x)
```

## Arguments

Х

A vector of values

#### Value

Returns the variance in log-space

## **Examples**

```
ExpVar(x = c(1, 2, 3))
```

 ${\tt FastRowScale}$ 

Scale and/or center matrix rowwise

## **Description**

Performs row scaling and/or centering. Equivalent to using t(scale(t(mat))) in R except in the case of NA values.

## Usage

```
FastRowScale(mat, center = TRUE, scale = TRUE, scale_max = 10)
```

### **Arguments**

mat A matrix

center a logical value indicating whether to center the rows scale a logical value indicating whether to scale the rows

scale\_max clip all values greater than scale\_max to scale\_max. Don't clip if Inf.

#### Value

Returns the center/scaled matrix

FeaturePlot 55

FeaturePlot

Visualize 'features' on a dimensional reduction plot

## **Description**

Colors single cells on a dimensional reduction plot according to a 'feature' (i.e. gene expression, PC scores, number of genes detected, etc.)

## Usage

```
FeaturePlot(
  object,
  features,
  dims = c(1, 2),
  cells = NULL,
  cols = if (blend) {
     c("lightgrey", "#ff0000", "#00ff00")
 } else {
    c("lightgrey", "blue")
 },
 pt.size = NULL,
  order = FALSE,
 min.cutoff = NA,
 max.cutoff = NA,
  reduction = NULL,
  split.by = NULL,
  keep.scale = "feature",
  shape.by = NULL,
  slot = "data",
  blend = FALSE,
  blend.threshold = 0.5,
  label = FALSE,
  label.size = 4,
  label.color = "black",
  repel = FALSE,
  ncol = NULL,
  coord.fixed = FALSE,
  by.col = TRUE,
  sort.cell = NULL,
  interactive = FALSE,
  combine = TRUE,
  raster = NULL,
  raster.dpi = c(512, 512)
)
```

56 FeaturePlot 1 8 1

#### **Arguments**

object Seurat object

features Vector of features to plot. Features can come from:

- An Assay feature (e.g. a gene name "MS4A1")
- A column name from meta.data (e.g. mitochondrial percentage "percent.mito")
- · A column name from a DimReduc object corresponding to the cell embedding values (e.g. the PC 1 scores - "PC 1")

Dimensions to plot, must be a two-length numeric vector specifying x- and ydimensions

cells Vector of cells to plot (default is all cells)

> The two colors to form the gradient over. Provide as string vector with the first color corresponding to low values, the second to high. Also accepts a Brewer color scale or vector of colors. Note: this will bin the data into number of colors provided. When blend is TRUE, takes anywhere from 1-3 colors:

> 1 color: Treated as color for double-negatives, will use default colors 2 and 3 for per-feature expression

> 2 colors: Treated as colors for per-feature expression, will use default color 1 for double-negatives

> **3+ colors:** First color used for double-negatives, colors 2 and 3 used for perfeature expression, all others ignored

pt.size Adjust point size for plotting

> Boolean determining whether to plot cells in order of expression. Can be useful if cells expressing given feature are getting buried.

min.cutoff, max.cutoff

Vector of minimum and maximum cutoff values for each feature, may specify quantile in the form of 'q##' where '##' is the quantile (eg, 'q1', 'q10')

reduction Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca

> A factor in object metadata to split the feature plot by, pass 'ident' to split by cell identity'; similar to the old FeatureHeatmap

keep.scale How to handle the color scale across multiple plots. Options are:

- "feature" (default; by row/feature scaling): The plots for each individual feature are scaled to the maximum expression of the feature across the conditions provided to 'split.by'.
- "all" (universal scaling): The plots for all features and conditions are scaled to the maximum expression value for the feature with the highest overall expression.
- NULL (no scaling): Each individual plot is scaled to the maximum expression value of the feature in the condition provided to 'split.by'. Be aware setting NULL will result in color scales that are not comparable between plots.

dims

cols

order

split.by

FeaturePlot 57

shape.by If NULL, all points are circles (default). You can specify any cell attribute (that

can be pulled with FetchData) allowing for both different colors and different

shapes on cells. Only applicable if raster = FALSE.

slot Which slot to pull expression data from?

blend Scale and blend expression values to visualize coexpression of two features

blend.threshold

The color cutoff from weak signal to strong signal; ranges from 0 to 1.

label Whether to label the clusters

label.size Sets size of labels

label.color Sets the color of the label text

repel Repel labels

ncol Number of columns to combine multiple feature plots to, ignored if split.by

is not NULL

coord.fixed Plot cartesian coordinates with fixed aspect ratio

by.col If splitting by a factor, plot the splits per column with the features as rows;

ignored if blend = TRUE

sort.cell Redundant with order. This argument is being deprecated. Please use order

instead.

interactive Launch an interactive FeaturePlot

combine Combine plots into a single patchworked ggplot object. If FALSE, return a list

of ggplot objects

raster Convert points to raster format, default is NULL which automatically rasterizes if

plotting more than 100,000 cells

raster.dpi Pixel resolution for rasterized plots, passed to geom\_scattermore(). Default is

c(512, 512).

### Value

A patchworked ggplot object if combine = TRUE; otherwise, a list of ggplot objects

#### Note

For the old do.hover and do.identify functionality, please see HoverLocator and CellSelector, respectively.

#### See Also

DimPlot HoverLocator CellSelector

### **Examples**

```
data("pbmc_small")
FeaturePlot(object = pbmc_small, features = 'PC_1')
```

58 FeatureScatter

 ${\it Feature Scatter}$ 

Scatter plot of single cell data

## Description

Creates a scatter plot of two features (typically feature expression), across a set of single cells. Cells are colored by their identity class. Pearson correlation between the two features is displayed above the plot.

## Usage

```
FeatureScatter(
  object,
  feature1,
  feature2,
  cells = NULL,
  shuffle = FALSE,
  seed = 1,
  group.by = NULL,
  cols = NULL,
  pt.size = 1,
  shape.by = NULL,
  span = NULL,
  smooth = FALSE,
  combine = TRUE,
  slot = "data",
  plot.cor = TRUE,
  raster = NULL,
  raster.dpi = c(512, 512),
  jitter = FALSE
)
```

## **Arguments**

| object   | Seurat object                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| feature1 | First feature to plot. Typically feature expression but can also be metrics, PC scores, etc anything that can be retreived with FetchData        |
| feature2 | Second feature to plot.                                                                                                                          |
| cells    | Cells to include on the scatter plot.                                                                                                            |
| shuffle  | Whether to randomly shuffle the order of points. This can be useful for crowded plots if points of interest are being buried. (default is FALSE) |
| seed     | Sets the seed if randomly shuffling the order of points.                                                                                         |
| group.by | Name of one or more metadata columns to group (color) cells by (for example, orig.ident); pass 'ident' to group by identity class                |
| cols     | Colors to use for identity class plotting.                                                                                                       |

FilterSlideSeq 59

| pt.size    | Size of the points on the plot                                                                                                               |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| shape.by   | Ignored for now                                                                                                                              |
| span       | Spline span in loess function call, if NULL, no spline added                                                                                 |
| smooth     | Smooth the graph (similar to smoothScatter)                                                                                                  |
| combine    | Combine plots into a single patchworked                                                                                                      |
| slot       | Slot to pull data from, should be one of 'counts', 'data', or 'scale.data'                                                                   |
| plot.cor   | Display correlation in plot title                                                                                                            |
| raster     | Convert points to raster format, default is NULL which will automatically use raster if the number of points plotted is greater than 100,000 |
| raster.dpi | Pixel resolution for rasterized plots, passed to geom_scattermore(). Default is $c(512,512)$ .                                               |
| jitter     | Jitter for easier visualization of crowded points (default is FALSE)                                                                         |

#### Value

A ggplot object

## **Examples**

```
data("pbmc_small")
FeatureScatter(object = pbmc_small, feature1 = 'CD9', feature2 = 'CD3E')
```

FilterSlideSeq

Filter stray beads from Slide-seq puck

# Description

This function is useful for removing stray beads that fall outside the main Slide-seq puck area. Essentially, it's a circular filter where you set a center and radius defining a circle of beads to keep. If the center is not set, it will be estimated from the bead coordinates (removing the 1st and 99th quantile to avoid skewing the center by the stray beads). By default, this function will display a SpatialDimPlot showing which cells were removed for easy adjustment of the center and/or radius.

## Usage

```
FilterSlideSeq(
  object,
  image = "image",
  center = NULL,
  radius = NULL,
  do.plot = TRUE
)
```

60 FindAllMarkers

## **Arguments**

| object  | Seurat object with slide-seq data                                                |
|---------|----------------------------------------------------------------------------------|
| image   | Name of the image where the coordinates are stored                               |
| center  | Vector specifying the x and y coordinates for the center of the inclusion circle |
| radius  | Radius of the circle of inclusion                                                |
| do.plot | Display a SpatialDimPlot with the cells being removed labeled.                   |

## Value

Returns a Seurat object with only the subset of cells that pass the circular filter

### **Examples**

```
## Not run:
# This example uses the ssHippo dataset which you can download
# using the SeuratData package.
library(SeuratData)
data('ssHippo')
# perform filtering of beads
ssHippo.filtered <- FilterSlideSeq(ssHippo, radius = 2300)
# This radius looks to small so increase and repeat until satisfied
## End(Not run)</pre>
```

FindAllMarkers

Gene expression markers for all identity classes

## **Description**

Finds markers (differentially expressed genes) for each of the identity classes in a dataset

## Usage

```
FindAllMarkers(
  object,
  assay = NULL,
  features = NULL,
  logfc.threshold = 0.25,
  test.use = "wilcox",
  slot = "data",
  min.pct = 0.1,
  min.diff.pct = -Inf,
  node = NULL,
  verbose = TRUE,
  only.pos = FALSE,
  max.cells.per.ident = Inf,
```

FindAllMarkers 61

```
random.seed = 1,
latent.vars = NULL,
min.cells.feature = 3,
min.cells.group = 3,
mean.fxn = NULL,
fc.name = NULL,
base = 2,
return.thresh = 0.01,
densify = FALSE,
...
)
```

### **Arguments**

object An object

assay Assay to use in differential expression testing

features Genes to test. Default is to use all genes

logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

test.use

Denotes which test to use. Available options are:

- "wilcox" : Identifies differentially expressed genes between two groups of cells using a Wilcoxon Rank Sum test (default)
- "bimod": Likelihood-ratio test for single cell gene expression, (McDavid et al., Bioinformatics, 2013)
- "roc": Identifies 'markers' of gene expression using ROC analysis. For each gene, evaluates (using AUC) a classifier built on that gene alone, to classify between two groups of cells. An AUC value of 1 means that expression values for this gene alone can perfectly classify the two groupings (i.e. Each of the cells in cells.1 exhibit a higher level than each of the cells in cells.2). An AUC value of 0 also means there is perfect classification, but in the other direction. A value of 0.5 implies that the gene has no predictive power to classify the two groups. Returns a 'predictive power' (abs(AUC-0.5) \* 2) ranked matrix of putative differentially expressed genes.
- "t": Identify differentially expressed genes between two groups of cells using the Student's t-test.
- "negbinom": Identifies differentially expressed genes between two groups of cells using a negative binomial generalized linear model. Use only for UMI-based datasets
- "poisson": Identifies differentially expressed genes between two groups of cells using a poisson generalized linear model. Use only for UMI-based datasets
- "LR": Uses a logistic regression framework to determine differentially expressed genes. Constructs a logistic regression model predicting group membership based on each feature individually and compares this to a null model with a likelihood ratio test.

62 FindAllMarkers

• "MAST": Identifies differentially expressed genes between two groups of cells using a hurdle model tailored to scRNA-seq data. Utilizes the MAST package to run the DE testing.

 "DESeq2": Identifies differentially expressed genes between two groups of cells based on a model using DESeq2 which uses a negative binomial distribution (Love et al, Genome Biology, 2014). This test does not support prefiltering of genes based on average difference (or percent detection rate) between cell groups. However, genes may be pre-filtered based on their minimum detection rate (min.pct) across both cell groups. To use this method,

please install DESeq2, using the instructions at https://bioconductor.org/packages/release/bioc/html/I

slot Slot to pull data from; note that if test.use is "negbinom", "poisson", or "DE-

Seq2", slot will be set to "counts"

min.pct only test genes that are detected in a minimum fraction of min.pct cells in either

of the two populations. Meant to speed up the function by not testing genes that

are very infrequently expressed. Default is 0.1

min.diff.pct only test genes that show a minimum difference in the fraction of detection

between the two groups. Set to -Inf by default

node A node to find markers for and all its children; requires BuildClusterTree to

have been run previously; replaces FindAllMarkersNode

verbose Print a progress bar once expression testing begins only.pos Only return positive markers (FALSE by default)

max.cells.per.ident

Down sample each identity class to a max number. Default is no downsampling.

Not activated by default (set to Inf)

random. seed Random seed for downsampling

latent.vars Variables to test, used only when test.use is one of 'LR', 'negbinom', 'pois-

son', or 'MAST'

min.cells.feature

Minimum number of cells expressing the feature in at least one of the two

groups, currently only used for poisson and negative binomial tests

min.cells.group

Minimum number of cells in one of the groups

mean. fxn Function to use for fold change or average difference calculation. If NULL, the

appropriate function will be chose according to the slot used

fc.name Name of the fold change, average difference, or custom function column in the

output data.frame. If NULL, the fold change column will be named according to the logarithm base (eg, "avg\_log2FC"), or if using the scale.data slot "avg\_diff".

base The base with respect to which logarithms are computed.

return. thresh Only return markers that have a p-value < return.thresh, or a power > return.thresh

(if the test is ROC)

densify Convert the sparse matrix to a dense form before running the DE test. This can

provide speedups but might require higher memory; default is FALSE

... Arguments passed to other methods and to specific DE methods

FindClusters 63

#### Value

Matrix containing a ranked list of putative markers, and associated statistics (p-values, ROC score, etc.)

#### **Examples**

```
data("pbmc_small")
# Find markers for all clusters
all.markers <- FindAllMarkers(object = pbmc_small)
head(x = all.markers)
## Not run:
# Pass a value to node as a replacement for FindAllMarkersNode
pbmc_small <- BuildClusterTree(object = pbmc_small)
all.markers <- FindAllMarkers(object = pbmc_small, node = 4)
head(x = all.markers)
## End(Not run)</pre>
```

FindClusters

Cluster Determination

#### **Description**

Identify clusters of cells by a shared nearest neighbor (SNN) modularity optimization based clustering algorithm. First calculate k-nearest neighbors and construct the SNN graph. Then optimize the modularity function to determine clusters. For a full description of the algorithms, see Waltman and van Eck (2013) *The European Physical Journal B*. Thanks to Nigel Delaney (evolvedmicrobe@github) for the rewrite of the Java modularity optimizer code in Rcpp!

## Usage

```
FindClusters(object, ...)
## Default S3 method:
FindClusters(
  object,
  modularity.fxn = 1,
  initial.membership = NULL,
  node.sizes = NULL,
  resolution = 0.8,
  method = "matrix",
  algorithm = 1,
  n.start = 10,
  n.iter = 10,
  random.seed = 0,
  group.singletons = TRUE,
  temp.file.location = NULL,
```

64 FindClusters

```
edge.file.name = NULL,
  verbose = TRUE,
)
## S3 method for class 'Seurat'
FindClusters(
  object,
  graph.name = NULL,
 modularity.fxn = 1,
  initial.membership = NULL,
  node.sizes = NULL,
  resolution = 0.8,
  method = "matrix",
  algorithm = 1,
  n.start = 10,
  n.iter = 10,
  random.seed = 0,
  group.singletons = TRUE,
  temp.file.location = NULL,
  edge.file.name = NULL,
  verbose = TRUE,
)
```

An object

#### **Arguments**

object

Arguments passed to other methods modularity function (1 = standard; 2 = alternative). initial.membership, node.sizes Parameters to pass to the Python leidenalg function. resolution Value of the resolution parameter, use a value above (below) 1.0 if you want to obtain a larger (smaller) number of communities. method Method for running leiden (defaults to matrix which is fast for small datasets). Enable method = "igraph" to avoid casting large data to a dense matrix. Algorithm for modularity optimization (1 = original Louvain algorithm; 2 = algorithm Louvain algorithm with multilevel refinement; 3 = SLM algorithm; 4 = Leiden algorithm). Leiden requires the leidenalg python. n.start Number of random starts. Maximal number of iterations per random start. n.iter random.seed Seed of the random number generator. group.singletons

Group singletons into nearest cluster. If FALSE, assign all singletons to a "singleton" group

FindConservedMarkers 65

```
temp.file.location
```

Directory where intermediate files will be written. Specify the ABSOLUTE

path.

edge.file.name Edge file to use as input for modularity optimizer jar.

verbose Print output

graph.name Name of graph to use for the clustering algorithm

#### **Details**

To run Leiden algorithm, you must first install the leidenalg python package (e.g. via pip install leidenalg), see Traag et al (2018).

#### Value

Returns a Seurat object where the idents have been updated with new cluster info; latest clustering results will be stored in object metadata under 'seurat\_clusters'. Note that 'seurat\_clusters' will be overwritten everytime FindClusters is run

FindConservedMarkers Finds markers that are conserved between the groups

## Description

Finds markers that are conserved between the groups

#### Usage

```
FindConservedMarkers(
  object,
  ident.1,
  ident.2 = NULL,
  grouping.var,
  assay = "RNA",
  slot = "data",
  min.cells.group = 3,
  meta.method = metap::minimump,
  verbose = TRUE,
  ...
)
```

### Arguments

object An object

ident.1 Identity class to define markers for

ident.2 A second identity class for comparison. If NULL (default) - use all other cells

for comparison.

grouping.var grouping variable

assay of assay to fetch data for (default is RNA)

slot Slot to pull data from; note that if test.use is "negbinom", "poisson", or "DE-

Seq2", slot will be set to "counts"

min.cells.group

Minimum number of cells in one of the groups

meta.method method for combining p-values. Should be a function from the metap package

(NOTE: pass the function, not a string)

verbose Print a progress bar once expression testing begins

... parameters to pass to FindMarkers

#### Value

data.frame containing a ranked list of putative conserved markers, and associated statistics (p-values within each group and a combined p-value (such as Fishers combined p-value or others from the metap package), percentage of cells expressing the marker, average differences). Name of group is appended to each associated output column (e.g. CTRL\_p\_val). If only one group is tested in the grouping.var, max and combined p-values are not returned.

#### **Examples**

```
## Not run:
data("pbmc_small")
pbmc_small
# Create a simulated grouping variable
pbmc_small[['groups']] <- sample(x = c('g1', 'g2'), size = ncol(x = pbmc_small), replace = TRUE)
FindConservedMarkers(pbmc_small, ident.1 = 0, ident.2 = 1, grouping.var = "groups")
## End(Not run)</pre>
```

FindIntegrationAnchors

Find integration anchors

### Description

Find a set of anchors between a list of Seurat objects. These anchors can later be used to integrate the objects using the IntegrateData function.

#### Usage

```
FindIntegrationAnchors(
  object.list = NULL,
  assay = NULL,
  reference = NULL,
```

```
anchor.features = 2000,
scale = TRUE,
normalization.method = c("LogNormalize", "SCT"),
sct.clip.range = NULL,
reduction = c("cca", "rpca", "rlsi"),
12.norm = TRUE,
dims = 1:30,
k.anchor = 5,
k.filter = 200,
k.score = 30,
max.features = 200,
nn.method = "annoy",
n.trees = 50,
eps = 0,
verbose = TRUE
```

## **Arguments**

object.list

A list of Seurat objects between which to find anchors for downstream integration.

assay

A vector of assay names specifying which assay to use when constructing anchors. If NULL, the current default assay for each object is used.

reference

A vector specifying the object/s to be used as a reference during integration. If NULL (default), all pairwise anchors are found (no reference/s). If not NULL, the corresponding objects in object.list will be used as references. When using a set of specified references, anchors are first found between each query and each reference. The references are then integrated through pairwise integration. Each query is then mapped to the integrated reference.

anchor.features

Can be either:

- A numeric value. This will call SelectIntegrationFeatures to select the provided number of features to be used in anchor finding
- A vector of features to be used as input to the anchor finding process

scale

Whether or not to scale the features provided. Only set to FALSE if you have previously scaled the features you want to use for each object in the object.list

normalization.method

Name of normalization method used: LogNormalize or SCT

sct.clip.range Numeric of length two specifying the min and max values the Pearson residual will be clipped to

Dimensional reduction to perform when finding anchors. Can be one of:

cca: Canonical correlation analysis

- rpca: Reciprocal PCA
- rlsi: Reciprocal LSI

12.norm

reduction

Perform L2 normalization on the CCA cell embeddings after dimensional reduction

| dims         | Which dimensions to use from the CCA to specify the neighbor search space                                   |
|--------------|-------------------------------------------------------------------------------------------------------------|
| k.anchor     | How many neighbors (k) to use when picking anchors                                                          |
| k.filter     | How many neighbors (k) to use when filtering anchors                                                        |
| k.score      | How many neighbors (k) to use when scoring anchors                                                          |
| max.features | The maximum number of features to use when specifying the neighborhood search space in the anchor filtering |
| nn.method    | Method for nearest neighbor finding. Options include: rann, annoy                                           |
| n.trees      | More trees gives higher precision when using annoy approximate nearest neighbor search                      |
| eps          | Error bound on the neighbor finding algorithm (from RANN/Annoy)                                             |
| verbose      | Print progress bars and output                                                                              |

#### **Details**

The main steps of this procedure are outlined below. For a more detailed description of the methodology, please see Stuart, Butler, et al Cell 2019: doi:10.1016/j.cell.2019.05.031; doi:10.1101/460147

First, determine anchor.features if not explicitly specified using SelectIntegrationFeatures. Then for all pairwise combinations of reference and query datasets:

- Perform dimensional reduction on the dataset pair as specified via the reduction parameter. If 12.norm is set to TRUE, perform L2 normalization of the embedding vectors.
- Identify anchors pairs of cells from each dataset that are contained within each other's neighborhoods (also known as mutual nearest neighbors).
- Filter low confidence anchors to ensure anchors in the low dimension space are in broad agreement with the high dimensional measurements. This is done by looking at the neighbors of each query cell in the reference dataset using max.features to define this space. If the reference cell isn't found within the first k.filter neighbors, remove the anchor.
- Assign each remaining anchor a score. For each anchor cell, determine the nearest k.score anchors within its own dataset and within its pair's dataset. Based on these neighborhoods, construct an overall neighbor graph and then compute the shared neighbor overlap between anchor and query cells (analogous to an SNN graph). We use the 0.01 and 0.90 quantiles on these scores to dampen outlier effects and rescale to range between 0-1.

### Value

Returns an AnchorSet object that can be used as input to IntegrateData.

```

## Arguments

object An object Arguments passed to other methods and to specific DE methods . . . Slot to pull data from; note that if test.use is "negbinom", "poisson", or "DEslot Seq2", slot will be set to "counts" counts Count matrix if using scale.data for DE tests. This is used for computing pct.1 and pct.2 and for filtering features based on fraction expressing cells.1 Vector of cell names belonging to group 1 cells.2 Vector of cell names belonging to group 2 features Genes to test. Default is to use all genes logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

test.use Denotes which test to use. Available options are:

- "wilcox" : Identifies differentially expressed genes between two groups of cells using a Wilcoxon Rank Sum test (default)
- "bimod": Likelihood-ratio test for single cell gene expression, (McDavid et al., Bioinformatics, 2013)

FindMarkers 73

• "roc": Identifies 'markers' of gene expression using ROC analysis. For each gene, evaluates (using AUC) a classifier built on that gene alone, to classify between two groups of cells. An AUC value of 1 means that expression values for this gene alone can perfectly classify the two groupings (i.e. Each of the cells in cells.1 exhibit a higher level than each of the cells in cells.2). An AUC value of 0 also means there is perfect classification, but in the other direction. A value of 0.5 implies that the gene has no predictive power to classify the two groups. Returns a 'predictive power' (abs(AUC-0.5) \* 2) ranked matrix of putative differentially expressed genes.

- "t": Identify differentially expressed genes between two groups of cells using the Student's t-test.
- "negbinom": Identifies differentially expressed genes between two groups of cells using a negative binomial generalized linear model. Use only for UMI-based datasets
- "poisson": Identifies differentially expressed genes between two groups of cells using a poisson generalized linear model. Use only for UMI-based datasets
- "LR": Uses a logistic regression framework to determine differentially expressed genes. Constructs a logistic regression model predicting group membership based on each feature individually and compares this to a null model with a likelihood ratio test.
- "MAST": Identifies differentially expressed genes between two groups of cells using a hurdle model tailored to scRNA-seq data. Utilizes the MAST package to run the DE testing.
- "DESeq2": Identifies differentially expressed genes between two groups of cells based on a model using DESeq2 which uses a negative binomial distribution (Love et al, Genome Biology, 2014). This test does not support prefiltering of genes based on average difference (or percent detection rate) between cell groups. However, genes may be pre-filtered based on their minimum detection rate (min.pct) across both cell groups. To use this method, please install DESeq2, using the instructions at https://bioconductor.org/packages/release/bioc/html/I

min.pct

only test genes that are detected in a minimum fraction of min.pct cells in either of the two populations. Meant to speed up the function by not testing genes that are very infrequently expressed. Default is 0.1

min.diff.pct

only test genes that show a minimum difference in the fraction of detection between the two groups. Set to -Inf by default

verbose

Print a progress bar once expression testing begins

only.pos

Only return positive markers (FALSE by default)

max.cells.per.ident

Down sample each identity class to a max number. Default is no downsampling. Not activated by default (set to Inf)

random.seed

Random seed for downsampling

latent.vars

Variables to test, used only when test.use is one of 'LR', 'negbinom', 'poisson', or 'MAST'

min.cells.feature

s.feature

Minimum number of cells expressing the feature in at least one of the two groups, currently only used for poisson and negative binomial tests

74 FindMarkers

min.cells.group Minimum number of cells in one of the groups pseudocount.use Pseudocount to add to averaged expression values when calculating logFC. 1 by default. fc.results data.frame from FoldChange densify Convert the sparse matrix to a dense form before running the DE test. This can provide speedups but might require higher memory; default is FALSE mean.fxn Function to use for fold change or average difference calculation. If NULL, the appropriate function will be chose according to the slot used fc.name Name of the fold change, average difference, or custom function column in the output data.frame. If NULL, the fold change column will be named according to the logarithm base (eg, "avg\_log2FC"), or if using the scale.data slot "avg\_diff". base The base with respect to which logarithms are computed. norm.method Normalization method for fold change calculation when slot is "data" Recalculate corrected UMI counts using minimum of the median UMIs when recorrect\_umi performing DE using multiple SCT objects; default is TRUE Identity class to define markers for; pass an object of class phylo or 'clusident.1 tertree' to find markers for a node in a cluster tree; passing 'clustertree' requires BuildClusterTree to have been run ident.2 A second identity class for comparison; if NULL, use all other cells for comparison; if an object of class phylo or 'clustertree' is passed to ident. 1, must pass a node to find markers for Regroup cells into a different identity class prior to performing differential exgroup.by pression (see example) Subset a particular identity class prior to regrouping. Only relevant if group.by subset.ident is set (see example)

assay Assay to use in differential expression testing

reduction Reduction to use in differential expression testing - will test for DE on cell em-

beddings

#### **Details**

p-value adjustment is performed using bonferroni correction based on the total number of genes in the dataset. Other correction methods are not recommended, as Seurat pre-filters genes using the arguments above, reducing the number of tests performed. Lastly, as Aaron Lun has pointed out, p-values should be interpreted cautiously, as the genes used for clustering are the same genes tested for differential expression.

### Value

data.frame with a ranked list of putative markers as rows, and associated statistics as columns (p-values, ROC score, etc., depending on the test used (test.use)). The following columns are always present:

FindMarkers 75

• avg\_logFC: log fold-chage of the average expression between the two groups. Positive values indicate that the gene is more highly expressed in the first group

- pct.1: The percentage of cells where the gene is detected in the first group
- pct. 2: The percentage of cells where the gene is detected in the second group
- p\_val\_adj: Adjusted p-value, based on bonferroni correction using all genes in the dataset

#### **Examples**

```
data("pbmc_small")
# Find markers for cluster 2
markers <- FindMarkers(object = pbmc_small, ident.1 = 2)
head(x = markers)

# Take all cells in cluster 2, and find markers that separate cells in the 'g1' group (metadata
# variable 'group')
markers <- FindMarkers(pbmc_small, ident.1 = "g1", group.by = 'groups', subset.ident = "2")
head(x = markers)

# Pass 'clustertree' or an object of class phylo to ident.1 and
# a node to ident.2 as a replacement for FindMarkersNode
if (requireNamespace("ape", quietly = TRUE)) {
   pbmc_small <- BuildClusterTree(object = pbmc_small)
   markers <- FindMarkers(object = pbmc_small, ident.1 = 'clustertree', ident.2 = 5)
   head(x = markers)
}</pre>
```

FindMultiModalNeighbors

Construct weighted nearest neighbor graph

# **Description**

This function will construct a weighted nearest neighbor (WNN) graph. For each cell, we identify the nearest neighbors based on a weighted combination of two modalities. Takes as input two dimensional reductions, one computed for each modality. Other parameters are listed for debugging, but can be left as default values.

# Usage

```
FindMultiModalNeighbors(
  object,
  reduction.list,
  dims.list,
  k.nn = 20,
  12.norm = TRUE,
  knn.graph.name = "wknn",
  snn.graph.name = "wsnn",
  weighted.nn.name = "weighted.nn",
  modality.weight.name = NULL,
  knn.range = 200,
  prune.SNN = 1/15,
  sd.scale = 1,
  cross.contant.list = NULL,
  smooth = FALSE,
  return.intermediate = FALSE,
  modality.weight = NULL,
  verbose = TRUE
)
```

# **Arguments**

| object         | A Seurat object                                                                               |
|----------------|-----------------------------------------------------------------------------------------------|
| reduction.list | A list of two dimensional reductions, one for each of the modalities to be integrated         |
| dims.list      | A list containing the dimensions for each reduction to use                                    |
| k.nn           | the number of multimodal neighbors to compute. 20 by default                                  |
| 12.norm        | Perform L2 normalization on the cell embeddings after dimensional reduction. TRUE by default. |
| knn.graph.name | Multimodal knn graph name                                                                     |
| snn.graph.name | Multimodal snn graph name                                                                     |

```
weighted.nn.name
                 Multimodal neighbor object name
modality.weight.name
                  Variable name to store modality weight in object meta data
                 The number of approximate neighbors to compute
knn.range
                 Cutoff not to discard edge in SNN graph
prune.SNN
sd.scale
                 The scaling factor for kernel width. 1 by default
cross.contant.list
                 Constant used to avoid divide-by-zero errors. 1e-4 by default
smooth
                 Smoothing modality score across each individual modality neighbors. FALSE
                 by default
return.intermediate
                  Store intermediate results in misc
modality.weight
                  A ModalityWeights object generated by FindModalityWeights
```

#### Value

Seurat object containing a nearest-neighbor object, KNN graph, and SNN graph - each based on a weighted combination of modalities.

Print progress bars and output

FindNeighbors

verbose

(Shared) Nearest-neighbor graph construction

### **Description**

Computes the k.param nearest neighbors for a given dataset. Can also optionally (via compute.SNN), construct a shared nearest neighbor graph by calculating the neighborhood overlap (Jaccard index) between every cell and its k.param nearest neighbors.

### Usage

```
FindNeighbors(object, ...)
## Default S3 method:
FindNeighbors(
  object,
  query = NULL,
  distance.matrix = FALSE,
  k.param = 20,
  return.neighbor = FALSE,
  compute.SNN = !return.neighbor,
  prune.SNN = 1/15,
  nn.method = "annoy",
```

```
n.trees = 50,
  annoy.metric = "euclidean",
  nn.eps = 0,
  verbose = TRUE,
  force.recalc = FALSE,
  12.norm = FALSE,
  cache.index = FALSE,
  index = NULL,
)
## S3 method for class 'Assay'
FindNeighbors(
 object,
  features = NULL,
  k.param = 20,
  return.neighbor = FALSE,
  compute.SNN = !return.neighbor,
  prune.SNN = 1/15,
  nn.method = "annoy",
  n.trees = 50,
  annoy.metric = "euclidean",
  nn.eps = 0,
  verbose = TRUE,
  force.recalc = FALSE,
  12.norm = FALSE,
  cache.index = FALSE,
)
## S3 method for class 'dist'
FindNeighbors(
  object,
  k.param = 20,
  return.neighbor = FALSE,
  compute.SNN = !return.neighbor,
  prune.SNN = 1/15,
  nn.method = "annoy",
  n.trees = 50,
  annoy.metric = "euclidean",
  nn.eps = 0,
  verbose = TRUE,
  force.recalc = FALSE,
 12.norm = FALSE,
  cache.index = FALSE,
)
```

```
## S3 method for class 'Seurat'
FindNeighbors(
  object,
  reduction = "pca",
  dims = 1:10,
  assay = NULL,
  features = NULL,
  k.param = 20,
  return.neighbor = FALSE,
  compute.SNN = !return.neighbor,
  prune.SNN = 1/15,
  nn.method = "annoy",
  n.trees = 50,
  annoy.metric = "euclidean",
  nn.eps = 0,
  verbose = TRUE,
  force.recalc = FALSE,
  do.plot = FALSE,
  graph.name = NULL,
  12.norm = FALSE,
  cache.index = FALSE,
)
```

# Arguments

object An object

... Arguments passed to other methods

query Matrix of data to query against object. If missing, defaults to object.

distance.matrix

Boolean value of whether the provided matrix is a distance matrix; note, for

objects of class dist, this parameter will be set automatically

k.param Defines k for the k-nearest neighbor algorithm

return.neighbor

Return result as Neighbor object. Not used with distance matrix input.

compute . SNN also compute the shared nearest neighbor graph

prune . SNN Sets the cutoff for acceptable Jaccard index when computing the neighborhood

overlap for the SNN construction. Any edges with values less than or equal to this will be set to 0 and removed from the SNN graph. Essentially sets the

stringency of pruning (0 — no pruning, 1 — prune everything).

nn.method Method for nearest neighbor finding. Options include: rann, annoy

n. trees More trees gives higher precision when using annoy approximate nearest neigh-

bor search

annoy.metric Distance metric for annoy. Options include: euclidean, cosine, manhattan, and

hamming

nn.eps Error bound when performing nearest neighbor seach using RANN; default of

0.0 implies exact nearest neighbor search

verbose Whether or not to print output to the console

force.recalc Force recalculation of (S)NN.

12. norm Take L2Norm of the data

cache . index Include cached index in returned Neighbor object (only relevant if return.neighbor

= TRUE)

index Precomputed index. Useful if querying new data against existing index to avoid

recomputing.

features Features to use as input for building the (S)NN; used only when dims is NULL

reduction Reduction to use as input for building the (S)NN

dims Dimensions of reduction to use as input

assay Assay to use in construction of (S)NN; used only when dims is NULL

do.plot Plot SNN graph on tSNE coordinates

graph.name Optional naming parameter for stored (S)NN graph (or Neighbor object, if re-

turn.neighbor = TRUE). Default is assay.name\_(s)nn. To store both the neighbor graph and the shared nearest neighbor (SNN) graph, you must supply a vector containing two names to the graph.name parameter. The first element in the vector will be used to store the nearest neighbor (NN) graph, and the second element used to store the SNN graph. If only one name is supplied, only the NN

graph is stored.

### Value

This function can either return a Neighbor object with the KNN information or a list of Graph objects with the KNN and SNN depending on the settings of return.neighbor and compute.SNN. When running on a Seurat object, this returns the Seurat object with the Graphs or Neighbor objects stored in their respective slots. Names of the Graph or Neighbor object can be found with Graphs or Neighbors.

### **Examples**

```
data("pbmc_small")
pbmc_small
# Compute an SNN on the gene expression level
pbmc_small <- FindNeighbors(pbmc_small, features = VariableFeatures(object = pbmc_small))
# More commonly, we build the SNN on a dimensionally reduced form of the data
# such as the first 10 principle components.

pbmc_small <- FindNeighbors(pbmc_small, reduction = "pca", dims = 1:10)</pre>
```

FindSpatiallyVariableFeatures

Find spatially variable features

## **Description**

Identify features whose variability in expression can be explained to some degree by spatial location.

# Usage

```
FindSpatiallyVariableFeatures(object, ...)
## Default S3 method:
FindSpatiallyVariableFeatures(
  object,
  spatial.location,
  selection.method = c("markvariogram", "moransi"),
  r.metric = 5,
  x.cuts = NULL,
 y.cuts = NULL,
  verbose = TRUE,
)
## S3 method for class 'Assay'
FindSpatiallyVariableFeatures(
  object,
  slot = "scale.data",
  spatial.location,
  selection.method = c("markvariogram", "moransi"),
  features = NULL,
  r.metric = 5,
  x.cuts = NULL,
  y.cuts = NULL,
  nfeatures = nfeatures,
  verbose = TRUE,
)
## S3 method for class 'Seurat'
FindSpatiallyVariableFeatures(
  object,
  assay = NULL,
  slot = "scale.data",
  features = NULL,
  image = NULL,
  selection.method = c("markvariogram", "moransi"),
```

82 FindSubCluster

```
r.metric = 5,
x.cuts = NULL,
y.cuts = NULL,
nfeatures = 2000,
verbose = TRUE,
...
)
```

# Arguments

object A Seurat object, assay, or expression matrix
... Arguments passed to other methods
spatial.location
Coordinates for each cell/spot/bead
selection.method

Method for selecting spatially variable features.

• markvariogram: See RunMarkVario for details

• moransi: See RunMoransI for details.

r.metric r value at which to report the "trans" value of the mark variogram

x.cuts Number of divisions to make in the x direction, helps define the grid over which

binning is performed

y.cuts Number of divisions to make in the y direction, helps define the grid over which

binning is performed

verbose Print messages and progress

slot Slot in the Assay to pull data from

features If provided, only compute on given features. Otherwise, compute for all fea-

tures.

nfeatures Number of features to mark as the top spatially variable.

assay Assay to pull the features (marks) from

image Name of image to pull the coordinates from

 ${\tt FindSubCluster}$ 

Find subclusters under one cluster

## Description

Find subclusters under one cluster

#### Usage

```
FindSubCluster(
  object,
  cluster,
  graph.name,
  subcluster.name = "sub.cluster",
  resolution = 0.5,
  algorithm = 1
)
```

### **Arguments**

object An object

cluster the cluster to be sub-clustered

graph.name Name of graph to use for the clustering algorithm

subcluster.name

the name of sub cluster added in the meta.data

resolution Value of the resolution parameter, use a value above (below) 1.0 if you want to

obtain a larger (smaller) number of communities.

algorithm Algorithm for modularity optimization (1 = original Louvain algorithm; 2 =

Louvain algorithm with multilevel refinement; 3 = SLM algorithm; 4 = Leiden

algorithm). Leiden requires the leidenalg python.

### Value

return a object with sub cluster labels in the sub-cluster.name variable

FindTransferAnchors Find transfer anchors

#### **Description**

Find a set of anchors between a reference and query object. These anchors can later be used to transfer data from the reference to query object using the TransferData object.

## Usage

```
FindTransferAnchors(
  reference,
  query,
  normalization.method = "LogNormalize",
  recompute.residuals = TRUE,
  reference.assay = NULL,
  reference.neighbors = NULL,
  query.assay = NULL,
```

```
reduction = "pcaproject",
  reference.reduction = NULL,
  project.query = FALSE,
  features = NULL,
  scale = TRUE,
  npcs = 30,
  12.norm = TRUE,
  dims = 1:30,
  k.anchor = 5.
  k.filter = 200,
  k.score = 30,
 max.features = 200,
  nn.method = "annoy",
  n.trees = 50,
  eps = 0,
  approx.pca = TRUE,
 mapping.score.k = NULL,
  verbose = TRUE
)
```

### **Arguments**

reference Seurat object to use as the reference query Seurat object to use as the query

normalization.method

Name of normalization method used: LogNormalize or SCT.

recompute.residuals

If using SCT as a normalization method, compute query Pearson residuals using the reference SCT model parameters.

reference.assay

Name of the Assay to use from reference

reference.neighbors

Name of the Neighbor to use from the reference. Optionally enables reuse of precomputed neighbors.

query.assay

Name of the Assay to use from query

reduction

Dimensional reduction to perform when finding anchors. Options are:

- pcaproject: Project the PCA from the reference onto the query. We recommend using PCA when reference and query datasets are from scRNA-seq
- Isiproject: Project the LSI from the reference onto the query. We recommend using LSI when reference and query datasets are from scATAC-seq. This requires that LSI has been computed for the reference dataset, and the same features (eg, peaks or genome bins) are present in both the reference and query. See RunTFIDF and RunSVD
- rpca: Project the PCA from the reference onto the query, and the PCA from the query onto the reference (reciprocal PCA projection).
- cca: Run a CCA on the reference and query

reference.reduction

Name of dimensional reduction to use from the reference if running the pcaproject workflow. Optionally enables reuse of precomputed reference dimensional reduction. If NULL (default), use a PCA computed on the reference object.

project.query Project the PCA from the query dataset onto the reference. Use only in rare

cases where the query dataset has a much larger cell number, but the reference dataset has a unique assay for transfer. In this case, the default features will be set to the variable features of the query object that are also present in the

reference.

features Features to use for dimensional reduction. If not specified, set as variable fea-

tures of the reference object which are also present in the query.

scale Scale query data.

Number of PCs to compute on reference if reference.reduction is not provided.

12.norm

Perform L2 normalization on the cell embeddings after dimensional reduction

dims Which dimensions to use from the reduction to specify the neighbor search space

k.anchor How many neighbors (k) to use when finding anchors

k.filter How many neighbors (k) to use when filtering anchors. Set to NA to turn off

filtering.

k.score How many neighbors (k) to use when scoring anchors

max.features The maximum number of features to use when specifying the neighborhood

search space in the anchor filtering

nn.method Method for nearest neighbor finding. Options include: rann, annoy

n.trees More trees gives higher precision when using annoy approximate nearest neigh-

bor search

eps Error bound on the neighbor finding algorithm (from RANN or RcppAnnoy)

approx.pca Use truncated singular value decomposition to approximate PCA

mapping.score.k

Compute and store nearest k query neighbors in the AnchorSet object that is returned. You can optionally set this if you plan on computing the mapping score and want to enable reuse of some downstream neighbor calculations to

make the mapping score function more efficient.

verbose Print progress bars and output

#### **Details**

The main steps of this procedure are outlined below. For a more detailed description of the methodology, please see Stuart, Butler, et al Cell 2019. doi:10.1016/j.cell.2019.05.031; doi:10.1101/460147

• Perform dimensional reduction. Exactly what is done here depends on the values set for the reduction and project.query parameters. If reduction = "pcaproject", a PCA is performed on either the reference (if project.query = FALSE) or the query (if project.query = TRUE), using the features specified. The data from the other dataset is then projected onto this learned PCA structure. If reduction = "cca", then CCA is performed on the reference

and query for this dimensional reduction step. If reduction = "lsiproject", the stored LSI dimension reduction in the reference object is used to project the query dataset onto the reference. If 12.norm is set to TRUE, perform L2 normalization of the embedding vectors.

- Identify anchors between the reference and query pairs of cells from each dataset that are contained within each other's neighborhoods (also known as mutual nearest neighbors).
- Filter low confidence anchors to ensure anchors in the low dimension space are in broad agreement with the high dimensional measurements. This is done by looking at the neighbors of each query cell in the reference dataset using max.features to define this space. If the reference cell isn't found within the first k.filter neighbors, remove the anchor.
- Assign each remaining anchor a score. For each anchor cell, determine the nearest k.score anchors within its own dataset and within its pair's dataset. Based on these neighborhoods, construct an overall neighbor graph and then compute the shared neighbor overlap between anchor and query cells (analogous to an SNN graph). We use the 0.01 and 0.90 quantiles on these scores to dampen outlier effects and rescale to range between 0-1.

#### Value

Returns an AnchorSet object that can be used as input to TransferData, IntegrateEmbeddings and MapQuery. The dimension reduction used for finding anchors is stored in the AnchorSet object and can be used for computing anchor weights in downstream functions. Note that only the requested dimensions are stored in the dimension reduction object in the AnchorSet. This means that if dims=2:20 is used, for example, the dimension of the stored reduction is 1:19.

)
pbmc.query <- AddMetaData(object = pbmc.query, metadata = predictions)
## End(Not run)</pre>
```

FindVariableFeatures Find variable features

## **Description**

Identifies features that are outliers on a 'mean variability plot'.

## Usage

```
FindVariableFeatures(object, ...)
## Default S3 method:
FindVariableFeatures(
  object,
  selection.method = "vst",
  loess.span = 0.3,
  clip.max = "auto",
 mean.function = FastExpMean,
  dispersion.function = FastLogVMR,
  num.bin = 20,
  binning.method = "equal_width",
  verbose = TRUE,
)
## S3 method for class 'Assay'
FindVariableFeatures(
  object,
  selection.method = "vst",
  loess.span = 0.3,
  clip.max = "auto",
  mean.function = FastExpMean,
  dispersion.function = FastLogVMR,
  num.bin = 20,
  binning.method = "equal_width",
  nfeatures = 2000,
 mean.cutoff = c(0.1, 8),
```

88 FindVariableFeatures

```
dispersion.cutoff = c(1, Inf),
  verbose = TRUE,
)
## S3 method for class 'SCTAssay'
FindVariableFeatures(object, nfeatures = 2000, ...)
## S3 method for class 'Seurat'
FindVariableFeatures(
  object,
  assay = NULL,
  selection.method = "vst",
  loess.span = 0.3,
  clip.max = "auto",
  mean.function = FastExpMean,
  dispersion.function = FastLogVMR,
  num.bin = 20,
  binning.method = "equal_width",
  nfeatures = 2000,
  mean.cutoff = c(0.1, 8),
  dispersion.cutoff = c(1, Inf),
  verbose = TRUE,
)
```

#### **Arguments**

object An object
... Arguments passed to other methods selection.method

How to choose top variable features. Choose one of:

- vst: First, fits a line to the relationship of log(variance) and log(mean) using local polynomial regression (loess). Then standardizes the feature values using the observed mean and expected variance (given by the fitted line). Feature variance is then calculated on the standardized values after clipping to a maximum (see clip.max parameter).
- mean.var.plot (mvp): First, uses a function to calculate average expression (mean.function) and dispersion (dispersion.function) for each feature. Next, divides features into num.bin (deafult 20) bins based on their average expression, and calculates z-scores for dispersion within each bin. The purpose of this is to identify variable features while controlling for the strong relationship between variability and average expression.
- dispersion (disp): selects the genes with the highest dispersion values

loess.span

(vst method) Loess span parameter used when fitting the variance-mean relationship

FoldChange 89

clip.max (vst method) After standardization values larger than clip.max will be set to

clip.max; default is 'auto' which sets this value to the square root of the number

of cells

mean.function Function to compute x-axis value (average expression). Default is to take the

mean of the detected (i.e. non-zero) values

dispersion.function

Function to compute y-axis value (dispersion). Default is to take the standard

deviation of all values

num.bin Total number of bins to use in the scaled analysis (default is 20)

binning.method Specifies how the bins should be computed. Available methods are:

• equal\_width: each bin is of equal width along the x-axis [default]

equal\_frequency: each bin contains an equal number of features (can increase statistical power to detect overdispersed features at high expression

values, at the cost of reduced resolution along the x-axis)

verbose show progress bar for calculations

nfeatures Number of features to select as top variable features; only used when selection.method

is set to 'dispersion' or 'vst'

mean.cutoff A two-length numeric vector with low- and high-cutoffs for feature means

dispersion.cutoff

A two-length numeric vector with low- and high-cutoffs for feature dispersions

assay Assay to use

#### **Details**

For the mean.var.plot method: Exact parameter settings may vary empirically from dataset to dataset, and based on visual inspection of the plot. Setting the y.cutoff parameter to 2 identifies features that are more than two standard deviations away from the average dispersion within a bin. The default X-axis function is the mean expression level, and for Y-axis it is the log(Variance/mean). All mean/variance calculations are not performed in log-space, but the results are reported in log-space - see relevant functions for exact details.

#### **Description**

Calculate log fold change and percentage of cells expressing each feature for different identity classes.

90 FoldChange

### Usage

```
FoldChange(object, ...)
## Default S3 method:
FoldChange(object, cells.1, cells.2, mean.fxn, fc.name, features = NULL, ...)
## S3 method for class 'Assay'
FoldChange(
  object,
  cells.1,
  cells.2,
  features = NULL,
  slot = "data",
  pseudocount.use = 1,
  fc.name = NULL,
 mean.fxn = NULL,
 base = 2,
 norm.method = NULL,
)
## S3 method for class 'DimReduc'
FoldChange(
  object,
  cells.1,
  cells.2,
  features = NULL,
  slot = NULL,
  pseudocount.use = 1,
  fc.name = NULL,
 mean.fxn = NULL,
  . . .
)
## S3 method for class 'Seurat'
FoldChange(
  object,
  ident.1 = NULL,
  ident.2 = NULL,
  group.by = NULL,
  subset.ident = NULL,
  assay = NULL,
  slot = "data",
  reduction = NULL,
  features = NULL,
  pseudocount.use = NULL,
  mean.fxn = NULL,
 base = 2,
```

FoldChange 91

```
fc.name = NULL,
    ...
)
```

# Arguments

| object         | A Seurat object                                                                                                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Arguments passed to other methods                                                                                                                                                                                   |
| cells.1        | Vector of cell names belonging to group 1                                                                                                                                                                           |
| cells.2        | Vector of cell names belonging to group 2                                                                                                                                                                           |
| mean.fxn       | Function to use for fold change or average difference calculation                                                                                                                                                   |
| fc.name        | Name of the fold change, average difference, or custom function column in the output data.frame                                                                                                                     |
| features       | Features to calculate fold change for. If NULL, use all features                                                                                                                                                    |
| slot           | Slot to pull data from                                                                                                                                                                                              |
| pseudocount.us | e                                                                                                                                                                                                                   |
|                | Pseudocount to add to averaged expression values when calculating logFC.                                                                                                                                            |
| base           | The base with respect to which logarithms are computed.                                                                                                                                                             |
| norm.method    | Normalization method for mean function selection when slot is "data"                                                                                                                                                |
| ident.1        | Identity class to calculate fold change for; pass an object of class phylo or 'clustertree' to calculate fold change for a node in a cluster tree; passing 'clustertree' requires BuildClusterTree to have been run |
| ident.2        | A second identity class for comparison; if NULL, use all other cells for comparison; if an object of class phylo or 'clustertree' is passed to ident.1, must pass a node to calculate fold change for               |
| group.by       | Regroup cells into a different identity class prior to calculating fold change (see example in FindMarkers)                                                                                                         |
| subset.ident   | Subset a particular identity class prior to regrouping. Only relevant if group.by is set (see example in FindMarkers)                                                                                               |
| assay          | Assay to use in fold change calculation                                                                                                                                                                             |
| reduction      | Reduction to use - will calculate average difference on cell embeddings                                                                                                                                             |

# **Details**

If the slot is scale.data or a reduction is specified, average difference is returned instead of log fold change and the column is named "avg\_diff". Otherwise, log2 fold change is returned with column named "avg\_log2\_FC".

## Value

Returns a data.frame

# See Also

FindMarkers

92 GetAssay

# **Examples**

```
data("pbmc_small")
FoldChange(pbmc_small, ident.1 = 1)
```

GetAssay

Get an Assay object from a given Seurat object.

# Description

Get an Assay object from a given Seurat object.

# Usage

```
GetAssay(object, ...)
## S3 method for class 'Seurat'
GetAssay(object, assay = NULL, ...)
```

# Arguments

object An object
... Arguments passed to other methods
assay Assay to get

#### Value

Returns an Assay object

# **Examples**

```
data("pbmc_small")
GetAssay(object = pbmc_small, assay = "RNA")
```

GetImage.SlideSeq 93

GetImage.SlideSeq

Get Image Data

#### **Description**

Get Image Data

### Usage

```
## S3 method for class 'SlideSeq'
GetImage(object, mode = c("grob", "raster", "plotly", "raw"), ...)
## S3 method for class 'STARmap'
GetImage(object, mode = c("grob", "raster", "plotly", "raw"), ...)
## S3 method for class 'VisiumV1'
GetImage(object, mode = c("grob", "raster", "plotly", "raw"), ...)
```

## Arguments

object An object

mode How to return the image; should accept one of "grob", "raster", "plotly", or

"raw"

Arguments passed to other methods

## See Also

SeuratObject::GetImage

GetIntegrationData

Get integration data

# **Description**

Get integration data

## Usage

```
GetIntegrationData(object, integration.name, slot)
```

# **Arguments**

```
object
                 Seurat object
integration.name
```

Name of integration object

Which slot in integration object to get

slot

94 GetResidual

## Value

Returns data from the requested slot within the integrated object

 ${\tt GetResidual}$ 

Calculate pearson residuals of features not in the scale.data

## **Description**

This function calls sctransform::get\_residuals.

# Usage

```
GetResidual(
  object,
  features,
  assay = NULL,
  umi.assay = NULL,
  clip.range = NULL,
  replace.value = FALSE,
  na.rm = TRUE,
  verbose = TRUE
)
```

#### **Arguments**

| object        | A seurat object                                                                                                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| features      | Name of features to add into the scale.data                                                                                                                                                                   |
| assay         | Name of the assay of the seurat object generated by SCTransform                                                                                                                                               |
| umi.assay     | Name of the assay of the seurat object containing UMI matrix and the default is RNA                                                                                                                           |
| clip.range    | Numeric of length two specifying the min and max values the Pearson residual will be clipped to                                                                                                               |
| replace.value | Recalculate residuals for all features, even if they are already present. Useful if you want to change the clip.range.                                                                                        |
| na.rm         | For features where there is no feature model stored, return NA for residual value in scale.data when na.rm = FALSE. When na.rm is TRUE, only return residuals for features with a model stored for all cells. |
| verbose       | Whether to print messages and progress bars                                                                                                                                                                   |

## Value

Returns a Seurat object containing Pearson residuals of added features in its scale.data

# See Also

```
get_residuals
```

### **Examples**

```
data("pbmc_small")
pbmc_small <- SCTransform(object = pbmc_small, variable.features.n = 20)
pbmc_small <- GetResidual(object = pbmc_small, features = c('MS4A1', 'TCL1A'))</pre>
```

GetTissueCoordinates.SlideSeq

Get Tissue Coordinates

## **Description**

Get Tissue Coordinates

#### Usage

```
## S3 method for class 'SlideSeq'
GetTissueCoordinates(object, ...)

## S3 method for class 'STARmap'
GetTissueCoordinates(object, qhulls = FALSE, ...)

## S3 method for class 'VisiumV1'
GetTissueCoordinates(
   object,
   scale = "lowres",
   cols = c("imagerow", "imagecol"),
   ...
)
```

## **Arguments**

```
object An object

... Arguments passed to other methods
qhulls return qhulls instead of centroids
scale A factor to scale the coordinates by; choose from: 'tissue', 'fiducial', 'hires',
'lowres', or NULL for no scaling

cols Columns of tissue coordinates data.frame to pull
```

#### See Also

SeuratObject::GetTissueCoordinates

96 GetTransferPredictions

GetTransferPredictions

Get the predicted identity

# Description

Utility function to easily pull out the name of the class with the maximum prediction. This is useful if you've set prediction.assay = TRUE in TransferData and want to have a vector with the predicted class.

# Usage

```
GetTransferPredictions(
  object,
  assay = "predictions",
  slot = "data",
  score.filter = 0.75
)
```

# Arguments

```
object Seurat object

assay Name of the assay holding the predictions

slot Slot of the assay in which the prediction scores are stored

score.filter Return "Unassigned" for any cell with a score less than this value
```

### Value

Returns a vector of predicted class names

## **Examples**

```
## Not run:
    prediction.assay <- TransferData(anchorset = anchors, refdata = reference$class)
    query[["predictions"]] <- prediction.assay
    query$predicted.id <- GetTransferPredictions(query)
## End(Not run)</pre>
```

Graph-class 97

| Graph-class | The Graph Class |
|-------------|-----------------|
|             |                 |

# Description

For more details, please see the documentation in SeuratObject

## See Also

```
SeuratObject::Graph-class
```

GroupCorrelation Compute the correlation of features broken down by groups with another covariate

# **Description**

Compute the correlation of features broken down by groups with another covariate

# Usage

```
GroupCorrelation(
  object,
  assay = NULL,
  slot = "scale.data",
  var = NULL,
  group.assay = NULL,
  min.cells = 5,
  ngroups = 6,
  do.plot = TRUE
)
```

# **Arguments**

| object      | Seurat object                                                                        |
|-------------|--------------------------------------------------------------------------------------|
| assay       | Assay to pull the data from                                                          |
| slot        | Slot in the assay to pull feature expression data from (counts, data, or scale.data) |
| var         | Variable with which to correlate the features                                        |
| group.assay | Compute the gene groups based off the data in this assay.                            |
| min.cells   | Only compute for genes in at least this many cells                                   |
| ngroups     | Number of groups to split into                                                       |
| do.plot     | Display the group correlation boxplot (via GroupCorrelationPlot)                     |
|             |                                                                                      |

#### Value

A Seurat object with the correlation stored in metafeatures

98 HoverLocator

GroupCorrelationPlot Boxplot of correlation of a variable (e.g. number of UMIs) with expression data

### **Description**

Boxplot of correlation of a variable (e.g. number of UMIs) with expression data

### Usage

```
GroupCorrelationPlot(
  object,
  assay = NULL,
  feature.group = "feature.grp",
  cor = "nCount_RNA_cor"
)
```

### **Arguments**

object Seurat object

assay Assay where the feature grouping info and correlations are stored

feature.group Name of the column in meta.features where the feature grouping info is stored

cor Name of the column in meta.features where correlation info is stored

#### Value

Returns a ggplot boxplot of correlations split by group

HoverLocator Hover Locator

## Description

Get quick information from a scatterplot by hovering over points

# Usage

```
HoverLocator(plot, information = NULL, axes = TRUE, dark.theme = FALSE, ...)
```

## **Arguments**

```
plot A ggplot2 plot

information An optional dataframe or matrix of extra information to be displayed on hover

axes Display or hide x- and y-axes

dark.theme Plot using a dark theme?

... Extra parameters to be passed to layout
```

HTODemux 99

#### See Also

layout ggplot\_build DimPlot FeaturePlot

#### **Examples**

```
## Not run:
data("pbmc_small")
plot <- DimPlot(object = pbmc_small)
HoverLocator(plot = plot, information = FetchData(object = pbmc_small, vars = 'percent.mito'))
## End(Not run)</pre>
```

**HTODemux** 

Demultiplex samples based on data from cell 'hashing'

# Description

Assign sample-of-origin for each cell, annotate doublets.

# Usage

```
HTODemux(
  object,
  assay = "HTO",
  positive.quantile = 0.99,
  init = NULL,
  nstarts = 100,
  kfunc = "clara",
  nsamples = 100,
  seed = 42,
  verbose = TRUE
)
```

#### **Arguments**

object Seurat object. Assumes that the hash tag oligo (HTO) data has been added and normalized.

assay Name of the Hashtag assay (HTO by default)

positive.quantile

The quantile of inferred 'negative' distribution for each hashtag - over which the

cell is considered 'positive'. Default is 0.99

init Initial number of clusters for hashtags. Default is the # of hashtag oligo names

+ 1 (to account for negatives)

nstarts value for k-means clustering (for kfunc = "kmeans"). 100 by default

100 HTOHeatmap

kfunc Clustering function for initial hashtag grouping. Default is "clara" for fast k-

medoids clustering on large applications, also support "kmeans" for kmeans

clustering

nsamples Number of samples to be drawn from the dataset used for clustering, for kfunc

= "clara"

seed Sets the random seed. If NULL, seed is not set

verbose Prints the output

### Value

The Seurat object with the following demultiplexed information stored in the meta data:

hash.maxID Name of hashtag with the highest signal

hash.secondID Name of hashtag with the second highest signal

hash.margin The difference between signals for hash.maxID and hash.secondID

classification Classification result, with doublets/multiplets named by the top two highest hashtags

classification.global Global classification result (singlet, doublet or negative)

hash.ID Classification result where doublet IDs are collapsed

#### See Also

**HTOHeatmap** 

## **Examples**

```
## Not run:
object <- HTODemux(object)
## End(Not run)</pre>
```

**HTOHeatmap** 

Hashtag oligo heatmap

## **Description**

Draws a heatmap of hashtag oligo signals across singlets/doublets/negative cells. Allows for the visualization of HTO demultiplexing results.

HTOHeatmap 101

### Usage

```
HTOHeatmap(
  object,
  assay = "HTO",
  classification = paste0(assay, "_classification"),
  global.classification = paste0(assay, "_classification.global"),
  ncells = 5000,
  singlet.names = NULL,
  raster = TRUE
)
```

### **Arguments**

object Seurat object. Assumes that the hash tag oligo (HTO) data has been added and

normalized, and demultiplexing has been run with HTODemux().

assay Hashtag assay name.

classification The naming for metadata column with classification result from HTODemux().

global.classification

The slot for metadata column specifying a cell as singlet/doublet/negative.

ncells Number of cells to plot. Default is to choose 5000 cells by random subsampling,

to avoid having to draw exceptionally large heatmaps.

singlet.names Namings for the singlets. Default is to use the same names as HTOs.

raster If true, plot with geom\_raster, else use geom\_tile. geom\_raster may look blurry

on some viewing applications such as Preview due to how the raster is interpolated. Set this to FALSE if you are encountering that issue (note that plots may

take longer to produce/render).

#### Value

Returns a ggplot2 plot object.

#### **Examples**

```
## Not run:
object <- HTODemux(object)
HTOHeatmap(object)
## End(Not run)</pre>
```

102 HVFInfo.SCTAssay

HVFInfo.SCTAssay

Get Variable Feature Information

# Description

Get variable feature information from SCTAssay objects

## Usage

```
## S3 method for class 'SCTAssay'
HVFInfo(object, selection.method, status = FALSE, ...)
```

## **Arguments**

object An object selection.method

Which method to pull. For HVFInfo and VariableFeatures, choose one from one of the following:

- "vst"
- "sctransform" or "sct"
- "mean.var.plot", "dispersion", "mvp", or "disp"

For SVFInfo and Spatially Variable Features, choose from:

- · "markvariogram"
- "moransi"

status

Add variable status to the resulting data frame

.. Arguments passed to other methods

## See Also

**HVFInfo** 

# **Examples**

```
# Get the HVF info directly from an SCTAssay object
pbmc_small <- SCTransform(pbmc_small)
HVFInfo(pbmc_small[["SCT"]], selection.method = 'sct')[1:5, ]</pre>
```

IFeaturePlot 103

| IFeaturePlot | Visualize features in dimensional reduction space interactively |  |
|--------------|-----------------------------------------------------------------|--|
|              |                                                                 |  |

# Description

Visualize features in dimensional reduction space interactively

# Usage

```
IFeaturePlot(object, feature, dims = c(1, 2), reduction = NULL, slot = "data")
```

# Arguments

| object    | Seurat object                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------|
| feature   | Feature to plot                                                                                       |
| dims      | Dimensions to plot, must be a two-length numeric vector specifying x- and y-dimensions                |
| reduction | Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca |
| slot      | Which slot to pull expression data from?                                                              |

## Value

Returns the final plot as a ggplot object

# Description

Visualize clusters or other categorical groupings in a spatial context

# Usage

```
ImageDimPlot(
  object,
  fov = NULL,
  boundaries = NULL,
  group.by = NULL,
  split.by = NULL,
  cols = NULL,
  shuffle.cols = FALSE,
  size = 0.5,
  molecules = NULL,
```

104 ImageDimPlot

```
mols.size = 0.1,
 mols.cols = NULL,
 mols.alpha = 1,
 nmols = 1000,
 alpha = 1,
 border.color = "white",
 border.size = NULL,
 na.value = "grey50",
 dark.background = TRUE,
 crop = FALSE,
 cells = NULL,
 overlap = FALSE,
 axes = FALSE,
 combine = TRUE,
 coord.fixed = TRUE
)
```

# Arguments

| object       | A Seurat object                                                                                                                                                                                                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fov          | Name of FOV to plot                                                                                                                                                                                                                                                                                              |
| boundaries   | A vector of segmentation boundaries per image to plot; can be a character vector, a named character vector, or a named list. Names should be the names of FOVs and values should be the names of segmentation boundaries                                                                                         |
| group.by     | Name of one or more metadata columns to group (color) cells by (for example, orig.ident); pass 'ident' to group by identity class                                                                                                                                                                                |
| split.by     | Name of a metadata column to split plot by; see FetchData for more details                                                                                                                                                                                                                                       |
| cols         | Vector of colors, each color corresponds to an identity class. This may also be a single character or numeric value corresponding to a palette as specified by brewer.pal.info. By default, ggplot2 assigns colors. We also include a number of palettes from the pals package. See DiscretePalette for details. |
| shuffle.cols | Randomly shuffle colors when a palette or vector of colors is provided to cols                                                                                                                                                                                                                                   |
| size         | Point size for cells when plotting centroids                                                                                                                                                                                                                                                                     |
| molecules    | A vector of molecules to plot                                                                                                                                                                                                                                                                                    |
| mols.size    | Point size for molecules                                                                                                                                                                                                                                                                                         |
| mols.cols    | A vector of color for molecules. The "Set1" palette from RColorBrewer is used by default.                                                                                                                                                                                                                        |
| mols.alpha   | Alpha value for molecules, should be between 0 and 1                                                                                                                                                                                                                                                             |
| nmols        | Max number of each molecule specified in 'molecules' to plot                                                                                                                                                                                                                                                     |
| alpha        | Alpha value, should be between 0 and 1; when plotting multiple boundaries, alpha is equivalent to max alpha                                                                                                                                                                                                      |
| border.color | Color of cell segmentation border; pass NA to suppress borders for segmentation-based plots                                                                                                                                                                                                                      |
| border.size  | Thickness of cell segmentation borders; pass NA to suppress borders for centroid-based plots                                                                                                                                                                                                                     |

ImageFeaturePlot 105

| na.value        | Color value for NA points when using custom scale                                                                                                 |  |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|--|
| dark.background |                                                                                                                                                   |  |
|                 | Set plot background to black                                                                                                                      |  |
| crop            | Crop the plots to area with cells only                                                                                                            |  |
| cells           | Vector of cells to plot (default is all cells)                                                                                                    |  |
| overlap         | Overlay boundaries from a single image to create a single plot; if TRUE, then boundaries are stacked in the order they're given (first is lowest) |  |
| axes            | Keep axes and panel background                                                                                                                    |  |
| combine         | Combine plots into a single patchwork ggplot object. If FALSE, return a list of ggplot objects                                                    |  |
| coord.fixed     | Plot cartesian coordinates with fixed aspect ratio                                                                                                |  |

#### Value

If combine = TRUE, a patchwork ggplot object; otherwise, a list of ggplot objects

ImageFeaturePlot Spatial Feature Plots

# **Description**

Visualize expression in a spatial context

# Usage

```
ImageFeaturePlot(
  object,
  features,
  fov = NULL,
 boundaries = NULL,
  cols = if (isTRUE(x = blend)) {
     c("lightgrey", "#ff0000", "#00ff00")
} else {
     c("lightgrey", "firebrick1")
},
 size = 0.5,
 min.cutoff = NA,
 max.cutoff = NA,
  split.by = NULL,
 molecules = NULL,
 mols.size = 0.1,
 mols.cols = NULL,
  nmols = 1000,
  alpha = 1,
```

106 ImageFeaturePlot

```
border.color = "white",
  border.size = NULL,
  dark.background = TRUE,
  blend = FALSE,
  blend.threshold = 0.5,
  crop = FALSE,
  cells = NULL,
  scale = c("feature", "all", "none"),
  overlap = FALSE,
  axes = FALSE,
  combine = TRUE,
  coord.fixed = TRUE
)
```

#### **Arguments**

object

Seurat object

features

Vector of features to plot. Features can come from:

- An Assay feature (e.g. a gene name "MS4A1")
- A column name from meta.data (e.g. mitochondrial percentage "per-
- A column name from a DimReduc object corresponding to the cell embedding values (e.g. the PC 1 scores - "PC\_1")

fov

Name of FOV to plot

boundaries

A vector of segmentation boundaries per image to plot; can be a character vector, a named character vector, or a named list. Names should be the names of FOVs and values should be the names of segmentation boundaries

cols

The two colors to form the gradient over. Provide as string vector with the first color corresponding to low values, the second to high. Also accepts a Brewer color scale or vector of colors. Note: this will bin the data into number of colors provided. When blend is TRUE, takes anywhere from 1-3 colors:

1 color: Treated as color for double-negatives, will use default colors 2 and 3 for per-feature expression

**2 colors:** Treated as colors for per-feature expression, will use default color 1 for double-negatives

3+ colors: First color used for double-negatives, colors 2 and 3 used for perfeature expression, all others ignored

size

Point size for cells when plotting centroids

min.cutoff, max.cutoff

Vector of minimum and maximum cutoff values for each feature, may specify quantile in the form of 'q##' where '##' is the quantile (eg, 'q1', 'q10')

A factor in object metadata to split the feature plot by, pass 'ident' to split by cell identity'; similar to the old FeatureHeatmap

molecules A vector of molecules to plot Point size for molecules

split.by

mols.size

IntegrateData 107

| mols.cols       | A vector of color for molecules. The "Set1" palette from RColorBrewer is used by default.                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| nmols           | Max number of each molecule specified in 'molecules' to plot                                                                                      |
| alpha           | Alpha value, should be between 0 and 1; when plotting multiple boundaries, alpha is equivalent to max alpha $$                                    |
| border.color    | Color of cell segmentation border; pass NA to suppress borders for segmentation-based plots $$                                                    |
| border.size     | Thickness of cell segmentation borders; pass NA to suppress borders for centroid-based plots $$                                                   |
| dark.background |                                                                                                                                                   |
|                 | Set plot background to black                                                                                                                      |
| blend           | Scale and blend expression values to visualize coexpression of two features                                                                       |
| blend.threshold |                                                                                                                                                   |
|                 | The color cutoff from weak signal to strong signal; ranges from 0 to 1.                                                                           |
| crop            | Crop the plots to area with cells only                                                                                                            |
| cells           | Vector of cells to plot (default is all cells)                                                                                                    |
| scale           | Set color scaling across multiple plots; choose from:                                                                                             |
|                 | <ul> <li>"feature": Plots per-feature are scaled across splits</li> </ul>                                                                         |
|                 | <ul> <li>"all": Plots per-feature are scaled across all features</li> </ul>                                                                       |
|                 | • "none": Plots are not scaled; <b>note</b> : setting scale to "none" will result in color scales that are <i>not</i> comparable between plots    |
|                 | Ignored if blend = TRUE                                                                                                                           |
| overlap         | Overlay boundaries from a single image to create a single plot; if TRUE, then boundaries are stacked in the order they're given (first is lowest) |
| axes            | Keep axes and panel background                                                                                                                    |
| combine         | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects                                                  |
| coord.fixed     | Plot cartesian coordinates with fixed aspect ratio                                                                                                |

# Value

If combine = TRUE, a patchwork ggplot object; otherwise, a list of ggplot objects

# Description

Perform dataset integration using a pre-computed AnchorSet.

108 IntegrateData

### Usage

```
IntegrateData(
   anchorset,
   new.assay.name = "integrated",
   normalization.method = c("LogNormalize", "SCT"),
   features = NULL,
   features.to.integrate = NULL,
   dims = 1:30,
   k.weight = 100,
   weight.reduction = NULL,
   sd.weight = 1,
   sample.tree = NULL,
   preserve.order = FALSE,
   eps = 0,
   verbose = TRUE
)
```

#### **Arguments**

anchorset An AnchorSet object generated by FindIntegrationAnchors

new.assay.name Name for the new assay containing the integrated data

normalization.method

Name of normalization method used: LogNormalize or SCT

features

Vector of features to use when computing the PCA to determine the weights. Only set if you want a different set from those used in the anchor finding process

features.to.integrate

Vector of features to integrate. By default, will use the features used in anchor finding.

dims

Number of dimensions to use in the anchor weighting procedure

k.weight

Number of neighbors to consider when weighting anchors

weight.reduction

Dimension reduction to use when calculating anchor weights. This can be one of:

- A string, specifying the name of a dimension reduction present in all objects to be integrated
- A vector of strings, specifying the name of a dimension reduction to use for each object to be integrated
- A vector of DimReduc objects, specifying the object to use for each object in the integration
- NULL, in which case a new PCA will be calculated and used to calculate anchor weights

Note that, if specified, the requested dimension reduction will only be used for calculating anchor weights in the first merge between reference and query, as the merged object will subsequently contain more cells than was in query, and weights will need to be calculated for all cells in the object.

IntegrateData 109

sd.weight

Controls the bandwidth of the Gaussian kernel for weighting

sample.tree

Specify the order of integration. Order of integration should be encoded in a matrix, where each row represents one of the pairwise integration steps. Negative numbers specify a dataset, positive numbers specify the integration results from a given row (the format of the merge matrix included in the hclust function output). For example: matrix(c(-2, 1, -3, -1), ncol = 2) gives:

Which would cause dataset 2 and 3 to be integrated first, then the resulting object integrated with dataset 1.

If NULL, the sample tree will be computed automatically.

preserve.order Do not reorder objects based on size for each pairwise integration.

eps Error bound on the neighbor finding algorithm (from RANN)

verbose Print progress bars and output

#### **Details**

The main steps of this procedure are outlined below. For a more detailed description of the methodology, please see Stuart, Butler, et al Cell 2019. doi:10.1016/j.cell.2019.05.031; doi:10.1101/460147

For pairwise integration:

- Construct a weights matrix that defines the association between each query cell and each anchor. These weights are computed as 1 the distance between the query cell and the anchor divided by the distance of the query cell to the k.weightth anchor multiplied by the anchor score computed in FindIntegrationAnchors. We then apply a Gaussian kernel width a bandwidth defined by sd.weight and normalize across all k.weight anchors.
- Compute the anchor integration matrix as the difference between the two expression matrices for every pair of anchor cells
- Compute the transformation matrix as the product of the integration matrix and the weights matrix.
- Subtract the transformation matrix from the original expression matrix.

For multiple dataset integration, we perform iterative pairwise integration. To determine the order of integration (if not specified via sample.tree), we

- Define a distance between datasets as the total number of cells in the smaller dataset divided by the total number of anchors between the two datasets.
- Compute all pairwise distances between datasets
- Cluster this distance matrix to determine a guide tree

110 IntegrateEmbeddings

#### Value

Returns a Seurat object with a new integrated Assay. If normalization.method = "LogNormalize", the integrated data is returned to the data slot and can be treated as log-normalized, corrected data. If normalization.method = "SCT", the integrated data is returned to the scale.data slot and can be treated as centered, corrected Pearson residuals.

# **Examples**

```
## Not run:
# to install the SeuratData package see https://github.com/satijalab/seurat-data
library(SeuratData)
data("panc8")
# panc8 is a merged Seurat object containing 8 separate pancreas datasets
# split the object by dataset
pancreas.list <- SplitObject(panc8, split.by = "tech")</pre>
# perform standard preprocessing on each object
for (i in 1:length(pancreas.list)) {
 pancreas.list[[i]] <- NormalizeData(pancreas.list[[i]], verbose = FALSE)</pre>
 pancreas.list[[i]] <- FindVariableFeatures(</pre>
   pancreas.list[[i]], selection.method = "vst",
    nfeatures = 2000, verbose = FALSE
 )
}
# find anchors
anchors <- FindIntegrationAnchors(object.list = pancreas.list)</pre>
# integrate data
integrated <- IntegrateData(anchorset = anchors)</pre>
## End(Not run)
```

#### Description

Perform dataset integration using a pre-computed Anchorset of specified low dimensional representations.

IntegrateEmbeddings 111

#### Usage

```
IntegrateEmbeddings(anchorset, ...)
## S3 method for class 'IntegrationAnchorSet'
IntegrateEmbeddings(
  anchorset,
  new.reduction.name = "integrated_dr",
  reductions = NULL,
 dims.to.integrate = NULL,
 k.weight = 100,
 weight.reduction = NULL,
  sd.weight = 1,
  sample.tree = NULL,
 preserve.order = FALSE,
  verbose = TRUE,
)
## S3 method for class 'TransferAnchorSet'
IntegrateEmbeddings(
  anchorset,
  reference,
 query,
  new.reduction.name = "integrated_dr",
  reductions = "pcaproject",
 dims.to.integrate = NULL,
 k.weight = 100,
 weight.reduction = NULL,
  reuse.weights.matrix = TRUE,
  sd.weight = 1,
 preserve.order = FALSE,
 verbose = TRUE,
)
```

#### **Arguments**

anchorset An AnchorSet object
... Reserved for internal use
new.reduction.name

Name for new integrated dimensional reduction.

reductions

Name of reductions to be integrated. For a TransferAnchorSet, this should be the name of a reduction present in the anchorset object (for example, "pcaproject"). For an IntegrationAnchorSet, this should be a DimReduc object containing all cells present in the anchorset object.

dims.to.integrate

Number of dimensions to return integrated values for

k.weight Number of neighbors to consider when weighting anchors weight.reduction

Dimension reduction to use when calculating anchor weights. This can be one of:

- A string, specifying the name of a dimension reduction present in all objects to be integrated
- A vector of strings, specifying the name of a dimension reduction to use for each object to be integrated
- A vector of DimReduc objects, specifying the object to use for each object in the integration
- NULL, in which case the full corrected space is used for computing anchor weights.

sd.weight
sample.tree

Controls the bandwidth of the Gaussian kernel for weighting

Specify the order of integration. Order of integration should be encoded in a matrix, where each row represents one of the pairwise integration steps. Negative numbers specify a dataset, positive numbers specify the integration results from a given row (the format of the merge matrix included in the hclust function output). For example: matrix(c(-2, 1, -3, -1), ncol = 2) gives:

Which would cause dataset 2 and 3 to be integrated first, then the resulting object integrated with dataset 1.

If NULL, the sample tree will be computed automatically.

preserve.order Do not reorder objects based on size for each pairwise integration.

verbose Print progress bars and output

reference Reference object used in anchorset construction query Query object used in anchorset construction

reuse.weights.matrix

Can be used in conjunction with the store.weights parameter in TransferData to reuse a precomputed weights matrix.

#### **Details**

The main steps of this procedure are identical to IntegrateData with one key distinction. When computing the weights matrix, the distance calculations are performed in the full space of integrated embeddings when integrating more than two datasets, as opposed to a reduced PCA space which is the default behavior in IntegrateData.

#### Value

When called on a TransferAnchorSet (from FindTransferAnchors), this will return the query object with the integrated embeddings stored in a new reduction. When called on an IntegrationAnchorSet (from IntegrateData), this will return a merged object with the integrated reduction stored.

IntegrationAnchorSet-class

The IntegrationAnchorSet Class

## **Description**

Inherits from the Anchorset class. Implemented mainly for method dispatch purposes. See AnchorSet for slot details.

IntegrationData-class The IntegrationData Class

# Description

The IntegrationData object is an intermediate storage container used internally throughout the integration procedure to hold bits of data that are useful downstream.

#### **Slots**

```
neighbors List of neighborhood information for cells (outputs of RANN::nn2)
weights Anchor weight matrix
integration.matrix Integration matrix
anchors Anchor matrix
offsets The offsets used to enable cell look up in downstream functions
objects.ncell Number of cells in each object in the object.list
sample.tree Sample tree used for ordering multi-dataset integration
```

**ISpatialDimPlot** 

Visualize clusters spatially and interactively

# **Description**

Visualize clusters spatially and interactively

```
ISpatialDimPlot(object, image = NULL, group.by = NULL, alpha = c(0.3, 1))
```

114 ISpatialFeaturePlot

#### **Arguments**

object Seurat object

image Name of the image to use in the plot

group.by Name of one or more metadata columns to group (color) cells by (for example,

orig.ident); pass 'ident' to group by identity class

alpha Controls opacity of spots. Provide as a vector specifying the min and max for

SpatialFeaturePlot. For SpatialDimPlot, provide a single alpha value for each

plot.

#### Value

Returns final plot as a ggplot object

ISpatialFeaturePlot

Visualize features spatially and interactively

## **Description**

Visualize features spatially and interactively

## Usage

```
ISpatialFeaturePlot(
  object,
  feature,
  image = NULL,
  slot = "data",
  alpha = c(0.1, 1)
)
```

#### **Arguments**

object Seurat object feature Feature to visualize

image Name of the image to use in the plot slot Which slot to pull expression data from?

alpha Controls opacity of spots. Provide as a vector specifying the min and max for

SpatialFeaturePlot. For SpatialDimPlot, provide a single alpha value for each

plot.

#### Value

Returns final plot as a ggplot object

JackStraw 115

JackStraw

Determine statistical significance of PCA scores.

## **Description**

Randomly permutes a subset of data, and calculates projected PCA scores for these 'random' genes. Then compares the PCA scores for the 'random' genes with the observed PCA scores to determine statistical signifiance. End result is a p-value for each gene's association with each principal component.

# Usage

```
JackStraw(
  object,
  reduction = "pca",
  assay = NULL,
  dims = 20,
  num.replicate = 100,
  prop.freq = 0.01,
  verbose = TRUE,
  maxit = 1000
)
```

#### **Arguments**

object Seurat object

reduction DimReduc to use. ONLY PCA CURRENTLY SUPPORTED.

assay Assay used to calculate reduction.

dims Number of PCs to compute significance for num.replicate Number of replicate samplings to perform

prop. freq Proportion of the data to randomly permute for each replicate

verbose Print progress bar showing the number of replicates that have been processed.

maxit maximum number of iterations to be performed by the irlba function of RunPCA

#### Value

Returns a Seurat object where JS(object = object[['pca']], slot = 'empirical') represents p-values for each gene in the PCA analysis. If ProjectPCA is subsequently run, JS(object = object[['pca']], slot = 'full') then represents p-values for all genes.

#### References

Inspired by Chung et al, Bioinformatics (2014)

116 JackStrawPlot

#### **Examples**

```
## Not run:
data("pbmc_small")
pbmc_small = suppressWarnings(JackStraw(pbmc_small))
head(JS(object = pbmc_small[['pca']], slot = 'empirical'))
## End(Not run)
```

JackStrawData-class

The JackStrawData Class

# **Description**

For more details, please see the documentation in SeuratObject

#### See Also

```
SeuratObject::JackStrawData-class
```

JackStrawPlot

JackStraw Plot

# Description

Plots the results of the JackStraw analysis for PCA significance. For each PC, plots a QQ-plot comparing the distribution of p-values for all genes across each PC, compared with a uniform distribution. Also determines a p-value for the overall significance of each PC (see Details).

```
JackStrawPlot(
  object,
  dims = 1:5,
  cols = NULL,
  reduction = "pca",
  xmax = 0.1,
  ymax = 0.3
)
```

L2CCA 117

#### **Arguments**

| object | Seurat object |
|--------|---------------|
| dims   | Dims to plot  |

cols Vector of colors, each color corresponds to an individual PC. This may also

be a single character or numeric value corresponding to a palette as specified by brewer.pal.info. By default, ggplot2 assigns colors. We also include a number of palettes from the pals package. See DiscretePalette for details.

reduction reduction to pull jackstraw info from X-axis maximum on each QQ plot.

Y-axis maximum on each QQ plot.

#### **Details**

Significant PCs should show a p-value distribution (black curve) that is strongly skewed to the left compared to the null distribution (dashed line) The p-value for each PC is based on a proportion test comparing the number of genes with a p-value below a particular threshold (score.thresh), compared with the proportion of genes expected under a uniform distribution of p-values.

#### Value

A ggplot object

#### Author(s)

Omri Wurtzel

## See Also

ScoreJackStraw

# Examples

```
data("pbmc_small")
JackStrawPlot(object = pbmc_small)
```

L2CCA

L2-Normalize CCA

#### **Description**

Perform 12 normalization on CCs

```
L2CCA(object, ...)
```

118 LabelClusters

#### **Arguments**

object Seurat object

... Additional parameters to L2Dim.

L2Dim *L2-normalization* 

## **Description**

Perform 12 normalization on given dimensional reduction

#### Usage

```
L2Dim(object, reduction, new.dr = NULL, new.key = NULL)
```

## Arguments

object Seurat object

reduction Dimensional reduction to normalize

new.dr name of new dimensional reduction to store (default is olddr.12)

new.key name of key for new dimensional reduction

#### Value

Returns a Seurat object

LabelClusters

Label clusters on a ggplot2-based scatter plot

## **Description**

Label clusters on a ggplot2-based scatter plot

```
LabelClusters(
  plot,
  id,
  clusters = NULL,
  labels = NULL,
  split.by = NULL,
  repel = TRUE,
  box = FALSE,
  geom = "GeomPoint",
  position = "median",
  ...
)
```

LabelPoints 119

## **Arguments**

| plot     | A ggplot2-based scatter plot                                                                                                                                                        |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id       | Name of variable used for coloring scatter plot                                                                                                                                     |
| clusters | Vector of cluster ids to label                                                                                                                                                      |
| labels   | Custom labels for the clusters                                                                                                                                                      |
| split.by | Split labels by some grouping label, useful when using facet_wrap or facet_grid                                                                                                     |
| repel    | Use geom_text_repel to create nicely-repelled labels                                                                                                                                |
| box      | Use geom_label/geom_label_repel (includes a box around the text labels)                                                                                                             |
| geom     | Name of geom to get X/Y aesthetic names for                                                                                                                                         |
| position | How to place the label if repel = FALSE. If "median", place the label at the median position. If "nearest" place the label at the position of the nearest data point to the median. |
|          | Extra parameters to geom_text_repel, such as size                                                                                                                                   |

## Value

A ggplot2-based scatter plot with cluster labels

## See Also

```
geom_text_repel geom_text
```

# **Examples**

```
data("pbmc_small")
plot <- DimPlot(object = pbmc_small)
LabelClusters(plot = plot, id = 'ident')</pre>
```

LabelPoints

Add text labels to a ggplot2 plot

# Description

Add text labels to a ggplot2 plot

```
LabelPoints(
  plot,
  points,
  labels = NULL,
  repel = FALSE,
  xnudge = 0.3,
  ynudge = 0.05,
  ...
)
```

120 LinkedPlots

## **Arguments**

| plot           | A ggplot2 plot with a GeomPoint layer                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| points         | A vector of points to label; if NULL, will use all points in the plot                                                                                   |
| labels         | A vector of labels for the points; if NULL, will use rownames of the data provided to the plot at the points selected                                   |
| repel          | Use geom_text_repel to create a nicely-repelled labels; this is slow when a lot of points are being plotted. If using repel, set xnudge and ynudge to 0 |
| xnudge, ynudge | Amount to nudge X and Y coordinates of labels by                                                                                                        |
|                | Extra parameters passed to geom_text                                                                                                                    |

#### Value

A ggplot object

#### See Also

```
geom_text
```

# **Examples**

```
data("pbmc_small")
ff <- TopFeatures(object = pbmc_small[['pca']])
cc <- TopCells(object = pbmc_small[['pca']])
plot <- FeatureScatter(object = pbmc_small, feature1 = ff[1], feature2 = ff[2])
LabelPoints(plot = plot, points = cc)</pre>
```

LinkedPlots

Visualize spatial and clustering (dimensional reduction) data in a linked, interactive framework

## **Description**

Visualize spatial and clustering (dimensional reduction) data in a linked, interactive framework

```
LinkedDimPlot(
  object,
  dims = 1:2,
  reduction = NULL,
  image = NULL,
  group.by = NULL,
  alpha = c(0.1, 1),
  combine = TRUE
)
```

LinkedPlots 121

```
LinkedFeaturePlot(
  object,
  feature,
  dims = 1:2,
  reduction = NULL,
  image = NULL,
  slot = "data",
  alpha = c(0.1, 1),
  combine = TRUE
)
```

# Arguments

| object    | Seurat object                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dims      | Dimensions to plot, must be a two-length numeric vector specifying x- and y-dimensions                                                                            |
| reduction | Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca                                                             |
| image     | Name of the image to use in the plot                                                                                                                              |
| group.by  | Name of one or more metadata columns to group (color) cells by (for example, orig.ident); pass 'ident' to group by identity class                                 |
| alpha     | Controls opacity of spots. Provide as a vector specifying the min and max for SpatialFeaturePlot. For SpatialDimPlot, provide a single alpha value for each plot. |
| combine   | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot objects                                                                  |
| feature   | Feature to visualize                                                                                                                                              |
| slot      | Which slot to pull expression data from?                                                                                                                          |

## Value

Returns final plots. If combine, plots are stiched together using CombinePlots; otherwise, returns a list of ggplot objects

# **Examples**

```
## Not run:
LinkedDimPlot(seurat.object)
LinkedFeaturePlot(seurat.object, feature = 'Hpca')
## End(Not run)
```

122 Load10X\_Spatial

Load10X\_Spatial

Load a 10x Genomics Visium Spatial Experiment into a Seurat object

# Description

Load a 10x Genomics Visium Spatial Experiment into a Seurat object

# Usage

```
Load10X_Spatial(
  data.dir,
  filename = "filtered_feature_bc_matrix.h5",
  assay = "Spatial",
  slice = "slice1",
  filter.matrix = TRUE,
  to.upper = FALSE,
  image = NULL,
  ...
)
```

## **Arguments**

| data.dir      | Directory containing the H5 file specified by filename and the image data in a subdirectory called spatial                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename      | Name of H5 file containing the feature barcode matrix                                                                                                                                                                                                                    |
| assay         | Name of the initial assay                                                                                                                                                                                                                                                |
| slice         | Name for the stored image of the tissue slice                                                                                                                                                                                                                            |
| filter.matrix | Only keep spots that have been determined to be over tissue                                                                                                                                                                                                              |
| to.upper      | Converts all feature names to upper case. This can provide an approximate conversion of mouse to human gene names which can be useful in an explorative analysis. For cross-species comparisons, orthologous genes should be identified across species and used instead. |
| image         | An object of class VisiumV1. Typically, an output from Read10X_Image                                                                                                                                                                                                     |
|               | Arguments passed to Read10X_h5                                                                                                                                                                                                                                           |

#### Value

A Seurat object

# **Examples**

```
## Not run:
data_dir <- 'path/to/data/directory'
list.files(data_dir) # Should show filtered_feature_bc_matrix.h5
Load10X_Spatial(data.dir = data_dir)</pre>
```

LoadAnnoyIndex 123

```
## End(Not run)
```

LoadAnnoyIndex

Load the Annoy index file

# Description

Load the Annoy index file

## Usage

```
LoadAnnoyIndex(object, file)
```

# Arguments

object Neighbor object

file Path to file with annoy index

## Value

Returns the Neighbor object with the index stored

LoadSTARmap

Load STARmap data

# Description

Load STARmap data

```
LoadSTARmap(
  data.dir,
  counts.file = "cell_barcode_count.csv",
  gene.file = "genes.csv",
  qhull.file = "qhulls.tsv",
  centroid.file = "centroids.tsv",
  assay = "Spatial",
  image = "image"
)
```

124 LoadXenium

# Arguments

data.dir location of data directory that contains the counts matrix, gene name, qhull, and centroid files.

counts.file name of file containing the counts matrix (csv)

gene.file name of file containing the gene names (csv)

qhull.file name of file containing the hull coordinates (tsv)

centroid.file name of file containing the centroid positions (tsv)

assay Name of assay to associate spatial data to

image Name of "image" object storing spatial coordinates

#### Value

A Seurat object

## See Also

**STARmap** 

LoadXenium

Read and Load 10x Genomics Xenium in-situ data

# **Description**

Read and Load 10x Genomics Xenium in-situ data

## Usage

```
LoadXenium(data.dir, fov = "fov", assay = "Xenium")
ReadXenium(
  data.dir,
  outs = c("matrix", "microns"),
  type = "centroids",
  mols.qv.threshold = 20
)
```

#### **Arguments**

data.dir Directory containing all Xenium output files with default filenames

fov FOV name assay Assay name

outs Types of molecular outputs to read; choose one or more of:

• "matrix": the counts matrix

• "microns": molecule coordinates

LocalStruct 125

type

Type of cell spatial coordinate matrices to read; choose one or more of:

- "centroids": cell centroids in pixel coordinate space
- "segmentations": cell segmentations in pixel coordinate space

mols.qv.threshold

Remove transcript molecules with a QV less than this threshold.  $QV \ge 20$  is the standard threshold used to construct the cell x gene count matrix.

#### Value

LoadXenium: A Seurat object

ReadXenium: A list with some combination of the following values:

- "matrix": a sparse matrix with expression data; cells are columns and features are rows
- "centroids": a data frame with cell centroid coordinates in three columns: "x", "y", and "cell"
- "pixels": a data frame with molecule pixel coordinates in three columns: "x", "y", and "gene"

LocalStruct

Calculate the local structure preservation metric

#### **Description**

Calculates a metric that describes how well the local structure of each group prior to integration is preserved after integration. This procedure works as follows: For each group, compute a PCA, compute the top num.neighbors in pca space, compute the top num.neighbors in corrected pca space, compute the size of the intersection of those two sets of neighbors. Return the average over all groups.

```
LocalStruct(
  object,
  grouping.var,
  idents = NULL,
  neighbors = 100,
  reduction = "pca",
  reduced.dims = 1:10,
  orig.dims = 1:10,
  verbose = TRUE
)
```

126 LogNormalize

#### **Arguments**

object Seurat object grouping.var Grouping variable

idents Optionally specify a set of idents to compute metric for neighbors Number of neighbors to compute in pca/corrected pca space

reduction Dimensional reduction to use for corrected space

reduced.dims Number of reduced dimensions to use orig.dims Number of PCs to use in original space

verbose Display progress bar

#### Value

Returns the average preservation metric

LogNormalize Normalize raw data

# Description

Normalize count data per cell and transform to log scale

#### Usage

```
LogNormalize(data, scale.factor = 10000, verbose = TRUE)
```

# **Arguments**

data Matrix with the raw count data scale.factor Scale the data. Default is 1e4

verbose Print progress

#### Value

Returns a matrix with the normalize and log transformed data

# **Examples**

```
mat <- matrix(data = rbinom(n = 25, size = 5, prob = 0.2), nrow = 5)
mat
mat_norm <- LogNormalize(data = mat)
mat_norm</pre>
```

LogVMR 127

LogVMR

Calculate the variance to mean ratio of logged values

## **Description**

Calculate the variance to mean ratio (VMR) in non-logspace (return answer in log-space)

## Usage

```
LogVMR(x, ...)
```

## **Arguments**

x A vector of values

... Other arguments (not used)

#### Value

Returns the VMR in log-space

# **Examples**

```
LogVMR(x = c(1, 2, 3))
```

MappingScore

Metric for evaluating mapping success

# **Description**

This metric was designed to help identify query cells that aren't well represented in the reference dataset. The intuition for the score is that we are going to project the query cells into a reference-defined space and then project them back onto the query. By comparing the neighborhoods before and after projection, we identify cells who's local neighborhoods are the most affected by this transformation. This could be because there is a population of query cells that aren't present in the reference or the state of the cells in the query is significantly different from the equivalent cell type in the reference.

128 MappingScore

#### Usage

```
MappingScore(anchors, ...)
## Default S3 method:
MappingScore(
  anchors,
  combined.object,
  query.neighbors,
  ref.embeddings,
  query.embeddings,
  kanchors = 50,
  ndim = 50,
  ksmooth = 100,
  ksnn = 20,
  snn.prune = 0,
  subtract.first.nn = TRUE,
  nn.method = "annoy",
  n.trees = 50,
  query.weights = NULL,
  verbose = TRUE,
)
## S3 method for class 'AnchorSet'
MappingScore(
  anchors,
  kanchors = 50,
  ndim = 50,
  ksmooth = 100,
  ksnn = 20,
  snn.prune = 0,
  subtract.first.nn = TRUE,
  nn.method = "annoy",
  n.trees = 50,
  query.weights = NULL,
  verbose = TRUE,
)
```

## **Arguments**

```
AnchorSet object or just anchor matrix from the Anchorset object returned from
anchors
                 FindTransferAnchors
                  Reserved for internal use
combined.object
                  Combined object (ref + query) from the Anchorset object returned
query.neighbors
                 Neighbors object computed on query cells
```

MapQuery 129

ref.embeddings Reference embeddings matrix query.embeddings

Query embeddings matrix

kanchors Number of anchors to use in projection steps when computing weights

ndim Number of dimensions to use when working with low dimensional projections

of the data

ksmooth Number of cells to average over when computing transition probabilities

ksnn Number of cells to average over when determining the kernel bandwidth from

the SNN graph

snn.prune Amount of pruning to apply to edges in SNN graph

subtract.first.nn

Option to the scoring function when computing distances to subtract the distance

to the first nearest neighbor

nn.method Nearest neighbor method to use (annoy or RANN)

n. trees More trees gives higher precision when using annoy approximate nearest neigh-

bor search

query.weights Query weights matrix for reuse verbose Display messages/progress

#### Value

Returns a vector of cell scores

Map Query cells to a reference

## **Description**

This is a convenience wrapper function around the following three functions that are often run together when mapping query data to a reference: TransferData, IntegrateEmbeddings, ProjectUMAP. Note that by default, the weight.reduction parameter for all functions will be set to the dimension reduction method used in the FindTransferAnchors function call used to construct the anchor object, and the dims parameter will be the same dimensions used to find anchors.

```
MapQuery(
   anchorset,
   query,
   reference,
   refdata = NULL,
   new.reduction.name = NULL,
   reference.reduction = NULL,
   reference.dims = NULL,
```

MapQuery

```
query.dims = NULL,
  reduction.model = NULL,
  transferdata.args = list(),
  integrateembeddings.args = list(),
  projectumap.args = list(),
  verbose = TRUE
)
```

#### **Arguments**

anchorset An AnchorSet object

query Query object used in anchorset construction reference Reference object used in anchorset construction

refdata Data to transfer. This can be specified in one of two ways:

- The reference data itself as either a vector where the names correspond to the reference cells, or a matrix, where the column names correspond to the reference cells.
- The name of the metadata field or assay from the reference object provided. This requires the reference parameter to be specified. If pulling assay data in this manner, it will pull the data from the data slot. To transfer data from other slots, please pull the data explicitly with GetAssayData and provide that matrix here.

new.reduction.name

Name for new integrated dimensional reduction.

reference.reduction

Name of reduction to use from the reference for neighbor finding

reference.dims Dimensions (columns) to use from reference query.dims Dimensions (columns) to use from query reduction.model

DimReduc object that contains the umap model

transferdata.args

A named list of additional arguments to TransferData

integrateembeddings.args

A named list of additional arguments to IntegrateEmbeddings

projectumap.args

A named list of additional arguments to ProjectUMAP

verbose Print progress bars and output

#### Value

Returns a modified query Seurat object containing:

- New Assays corresponding to the features transferred and/or their corresponding prediction scores from TransferData
- An integrated reduction from IntegrateEmbeddings
- A projected UMAP reduction of the query cells projected into the reference UMAP using ProjectUMAP

merge.SCTAssay 131

merge.SCTAssay

Merge SCTAssay objects

# Description

Merge SCTAssay objects

# Usage

```
## S3 method for class 'SCTAssay'
merge(
    x = NULL,
    y = NULL,
    add.cell.ids = NULL,
    merge.data = TRUE,
    na.rm = TRUE,
    ...
)
```

# Arguments

| X            | A Seurat object                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| У            | A single Seurat object or a list of Seurat objects                                                                                                                          |
| add.cell.ids | A character vector of length( $x = c(x, y)$ ); appends the corresponding values to the start of each objects' cell names                                                    |
| merge.data   | Merge the data slots instead of just merging the counts (which requires renormalization); this is recommended if the same normalization approach was applied to all objects |
| na.rm        | If na.rm = TRUE, this will only preserve residuals that are present in all SCTAssays being merged. Otherwise, missing residuals will be populated with NAs.                 |
|              | Arguments passed to other methods                                                                                                                                           |

MetaFeature

Aggregate expression of multiple features into a single feature

# Description

Calculates relative contribution of each feature to each cell for given set of features.

MinMax

## Usage

```
MetaFeature(
  object,
  features,
  meta.name = "metafeature",
  cells = NULL,
  assay = NULL,
  slot = "data"
)
```

## **Arguments**

object A Seurat object

features List of features to aggregate

meta.name Name of column in metadata to store metafeature

cells List of cells to use (default all cells)

assay Which assay to use

slot Which slot to take data from (default data)

## Value

Returns a Seurat object with metafeature stored in objet metadata

## **Examples**

```
data("pbmc_small")
pbmc_small <- MetaFeature(
  object = pbmc_small,
  features = c("LTB", "EAF2"),
  meta.name = 'var.aggregate'
)
head(pbmc_small[[]])</pre>
```

MinMax

Apply a ceiling and floor to all values in a matrix

# Description

Apply a ceiling and floor to all values in a matrix

```
MinMax(data, min, max)
```

MixingMetric 133

## **Arguments**

| data | Matrix or data frame                                      |
|------|-----------------------------------------------------------|
| min  | all values below this min value will be replaced with min |
| max  | all values above this max value will be replaced with max |

#### Value

Returns matrix after performing these floor and ceil operations

#### **Examples**

```
mat <- matrix(data = rbinom(n = 25, size = 20, prob = 0.2 ), nrow = 5)
mat
MinMax(data = mat, min = 4, max = 5)</pre>
```

MixingMetric

Calculates a mixing metric

## **Description**

Here we compute a measure of how well mixed a composite dataset is. To compute, we first examine the local neighborhood for each cell (looking at max.k neighbors) and determine for each group (could be the dataset after integration) the k nearest neighbor and what rank that neighbor was in the overall neighborhood. We then take the median across all groups as the mixing metric per cell.

#### Usage

```
MixingMetric(
  object,
  grouping.var,
  reduction = "pca",
  dims = 1:2,
  k = 5,
  max.k = 300,
  eps = 0,
  verbose = TRUE
)
```

# Arguments

object Seurat object

grouping.var Grouping variable for dataset

reduction Which dimensionally reduced space to use

dims Dimensions to use

134 MixscapeHeatmap

| k       | Neighbor number to examine per group                      |
|---------|-----------------------------------------------------------|
| max.k   | Maximum size of local neighborhood to compute             |
| eps     | Error bound on the neighbor finding algorithm (from RANN) |
| verbose | Displays progress bar                                     |

# Value

Returns a vector of values of the mixing metric for each cell

| MixscapeHeatmap | Differential expression heatmap for mixscape |  |
|-----------------|----------------------------------------------|--|
|                 |                                              |  |

# Description

Draws a heatmap of single cell feature expression with cells ordered by their mixscape ko probabilities.

## Usage

```
MixscapeHeatmap(
  object,
  ident.1 = NULL,
  ident.2 = NULL,
 balanced = TRUE,
  logfc.threshold = 0.25,
  assay = "RNA",
 max.genes = 100,
  test.use = "wilcox",
 max.cells.group = NULL,
 order.by.prob = TRUE,
 group.by = NULL,
 mixscape.class = "mixscape_class",
 prtb.type = "KO",
  fc.name = "avg_log2FC",
  pval.cutoff = 0.05,
)
```

## **Arguments**

| object  | An object                                                                                                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ident.1 | Identity class to define markers for; pass an object of class phylo or 'clustertree' to find markers for a node in a cluster tree; passing 'clustertree' requires BuildClusterTree to have been run |
| ident.2 | A second identity class for comparison; if NULL, use all other cells for comparison; if an object of class phylo or 'clustertree' is passed to ident.1, must pass a node to find markers for        |

MixscapeHeatmap 135

balanced Plot an equal number of genes with both groups of cells.

logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

assay Assay to use in differential expression testing

max.genes Total number of DE genes to plot.

test.use Denotes which test to use. Available options are:

- "wilcox": Identifies differentially expressed genes between two groups of cells using a Wilcoxon Rank Sum test (default)
- "bimod": Likelihood-ratio test for single cell gene expression, (McDavid et al., Bioinformatics, 2013)
- "roc": Identifies 'markers' of gene expression using ROC analysis. For each gene, evaluates (using AUC) a classifier built on that gene alone, to classify between two groups of cells. An AUC value of 1 means that expression values for this gene alone can perfectly classify the two groupings (i.e. Each of the cells in cells.1 exhibit a higher level than each of the cells in cells.2). An AUC value of 0 also means there is perfect classification, but in the other direction. A value of 0.5 implies that the gene has no predictive power to classify the two groups. Returns a 'predictive power' (abs(AUC-0.5) \* 2) ranked matrix of putative differentially expressed genes.
- "t": Identify differentially expressed genes between two groups of cells using the Student's t-test.
- "negbinom": Identifies differentially expressed genes between two groups of cells using a negative binomial generalized linear model. Use only for UMI-based datasets
- "poisson": Identifies differentially expressed genes between two groups of cells using a poisson generalized linear model. Use only for UMI-based datasets
- "LR": Uses a logistic regression framework to determine differentially expressed genes. Constructs a logistic regression model predicting group membership based on each feature individually and compares this to a null model with a likelihood ratio test.
- "MAST": Identifies differentially expressed genes between two groups of cells using a hurdle model tailored to scRNA-seq data. Utilizes the MAST package to run the DE testing.
- "DESeq2": Identifies differentially expressed genes between two groups of cells based on a model using DESeq2 which uses a negative binomial distribution (Love et al, Genome Biology, 2014). This test does not support prefiltering of genes based on average difference (or percent detection rate) between cell groups. However, genes may be pre-filtered based on their minimum detection rate (min.pct) across both cell groups. To use this method, please install DESeq2, using the instructions at https://bioconductor.org/packages/release/bioc/html/I

max.cells.group

Number of cells per identity to plot.

136 MixscapeLDA

| order.by.prob  | Order cells on heatmap based on their mixscape knockout probability from highest to lowest score.                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------|
| group.by       | (Deprecated) Option to split densities based on mixscape classification. Please use mixscape.class instead                |
| mixscape.class | metadata column with mixscape classifications.                                                                            |
| prtb.type      | specify type of CRISPR perturbation expected for labeling mixscape classifications. Default is KO.                        |
| fc.name        | Name of the fold change, average difference, or custom function column in the output data.frame. Default is $avg\_log2FC$ |
| pval.cutoff    | P-value cut-off for selection of significantly DE genes.                                                                  |
|                | Arguments passed to other methods and to specific DE methods                                                              |

# Value

A ggplot object.

MixscapeLDA

Linear discriminant analysis on pooled CRISPR screen data.

## **Description**

This function performs unsupervised PCA on each mixscape class separately and projects each subspace onto all cells in the data. Finally, it uses the first 10 principle components from each projection as input to lda in MASS package together with mixscape class labels.

```
MixscapeLDA(
object,
assay = NULL,
ndims.print = 1:5,
nfeatures.print = 30,
reduction.key = "LDA_",
seed = 42,
pc.assay = "PRTB",
labels = "gene",
nt.label = "NT",
npcs = 10,
verbose = TRUE,
logfc.threshold = 0.25
)
```

#### **Arguments**

object An object of class Seurat.

assay Assay to use for performing Linear Discriminant Analysis (LDA).

ndims.print Number of LDA dimensions to print.

nfeatures.print

Number of features to print for each LDA component.

reduction.key Reduction key name. seed Value for random seed

pc.assay Assay to use for running Principle components analysis.

labels Meta data column with target gene class labels.

nt.label Name of non-targeting cell class.

npcs Number of principle components to use.

verbose Print progress bar.

logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold

speeds up the function, but can miss weaker signals.

#### Value

Returns a Seurat object with LDA added in the reduction slot.

ModalityWeights-class The ModalityWeights Class

# **Description**

The ModalityWeights class is an intermediate data storage class that stores the modality weight and other related information needed for performing downstream analyses - namely data integration (FindModalityWeights) and data transfer (FindMultiModalNeighbors).

#### **Slots**

modality.weight.list A list of modality weights value from all modalities

modality.assay Names of assays for the list of dimensional reductions

params A list of parameters used in the FindModalityWeights

score.matrix a list of score matrices representing cross and within-modality prediction score, and kernel value

command Store log of parameters that were used

138 MULTIseqDemux

| MULTIseqDemux | Demultiplex samples based on classification method from MULTI-seq |
|---------------|-------------------------------------------------------------------|
|               | (McGinnis et al., bioRxiv 2018)                                   |

# Description

Identify singlets, doublets and negative cells from multiplexing experiments. Annotate singlets by tags.

# Usage

```
MULTIseqDemux(
  object,
  assay = "HTO",
  quantile = 0.7,
  autoThresh = FALSE,
  maxiter = 5,
  qrange = seq(from = 0.1, to = 0.9, by = 0.05),
  verbose = TRUE
)
```

## **Arguments**

| object     | Seurat object. Assumes that the specified assay data has been added                                         |
|------------|-------------------------------------------------------------------------------------------------------------|
| assay      | Name of the multiplexing assay (HTO by default)                                                             |
| quantile   | The quantile to use for classification                                                                      |
| autoThresh | Whether to perform automated threshold finding to define the best quantile. Default is $\ensuremath{FALSE}$ |
| maxiter    | Maximum number of iterations if autoThresh = TRUE. Default is 5                                             |
| qrange     | A range of possible quantile values to try if autoThresh = TRUE                                             |
| verbose    | Prints the output                                                                                           |

#### Value

A Seurat object with demultiplexing results stored at object\$MULTI\_ID

#### References

```
https://www.biorxiv.org/content/10.1101/387241v1
```

# **Examples**

```
## Not run:
object <- MULTIseqDemux(object)
## End(Not run)</pre>
```

Neighbor-class 139

Neighbor-class The Neighbor Class

## **Description**

For more details, please see the documentation in SeuratObject

#### See Also

```
SeuratObject::Neighbor-class
```

NNPlot

Highlight Neighbors in DimPlot

# **Description**

It will color the query cells and the neighbors of the query cells in the DimPlot

# Usage

```
NNPlot(
  object,
  reduction,
  nn.idx,
  query.cells,
  dims = 1:2,
  label = FALSE,
  label.size = 4,
  repel = FALSE,
  sizes.highlight = 2,
  pt.size = 1,
  cols.highlight = c("#377eb8", "#e41a1c"),
  na.value = "#bdbdbd",
 order = c("self", "neighbors", "other"),
  show.all.cells = TRUE,
)
```

# Arguments

object Seurat object

reduction Which dimensionality reduction to use. If not specified, first searches for umap, then tsne, then pca

nn.idx the neighbor index of all cells

140 NormalizeData

query.cells cells used to find their neighbors

dims Dimensions to plot, must be a two-length numeric vector specifying x- and y-

dimensions

label Whether to label the clusters

label.size Sets size of labels repel Repel labels

sizes.highlight

Size of highlighted cells; will repeat to the length groups in cells.highlight

pt.size Adjust point size for plotting

cols.highlight A vector of colors to highlight the cells as; will repeat to the length groups in

cells.highlight

na. value Color value for NA points when using custom scale

order Specify the order of plotting for the idents. This can be useful for crowded plots

if points of interest are being buried. Provide either a full list of valid idents or a

subset to be plotted last (on top)

show.all.cells Show all cells or only query and neighbor cells

... Extra parameters passed to DimPlot

#### Value

A patchworked ggplot object if combine = TRUE; otherwise, a list of ggplot objects

NormalizeData

Normalize Data

#### **Description**

Normalize the count data present in a given assay.

```
NormalizeData(object, ...)
## Default S3 method:
NormalizeData(
  object,
  normalization.method = "LogNormalize",
  scale.factor = 10000,
  margin = 1,
  block.size = NULL,
  verbose = TRUE,
  ...
)
```

NormalizeData 141

```
## S3 method for class 'Assay'
NormalizeData(
  object,
  normalization.method = "LogNormalize",
  scale.factor = 10000,
  margin = 1,
  verbose = TRUE,
)
## S3 method for class 'Seurat'
NormalizeData(
  object,
  assay = NULL,
  normalization.method = "LogNormalize",
  scale.factor = 10000,
  margin = 1,
  verbose = TRUE,
)
```

#### **Arguments**

object An object

... Arguments passed to other methods

normalization.method

Method for normalization.

- LogNormalize: Feature counts for each cell are divided by the total counts for that cell and multiplied by the scale.factor. This is then natural-log transformed using log1p.
- CLR: Applies a centered log ratio transformation
- RC: Relative counts. Feature counts for each cell are divided by the total counts for that cell and multiplied by the scale.factor. No log-transformation is applied. For counts per million (CPM) set scale.factor = 1e6

scale.factor Sets the scale factor for cell-level normalization

margin If performing CLR normalization, normalize across features (1) or cells (2)

block.size How many cells should be run in each chunk, will try to split evenly across

threads

verbose display progress bar for normalization procedure

assay Name of assay to use

#### Value

Returns object after normalization

PCASigGenes PCASigGenes

## **Examples**

```
## Not run:
data("pbmc_small")
pbmc_small
pmbc_small <- NormalizeData(object = pbmc_small)
## End(Not run)</pre>
```

**PCASigGenes** 

Significant genes from a PCA

## **Description**

Returns a set of genes, based on the JackStraw analysis, that have statistically significant associations with a set of PCs.

# Usage

```
PCASigGenes(
  object,
  pcs.use,
  pval.cut = 0.1,
  use.full = FALSE,
  max.per.pc = NULL
)
```

## **Arguments**

| object     | Seurat object                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------|
| pcs.use    | PCS to use.                                                                                                                 |
| pval.cut   | P-value cutoff                                                                                                              |
| use.full   | Use the full list of genes (from the projected PCA). Assumes that ProjectDim has been run. Currently, must be set to FALSE. |
| max.per.pc | Maximum number of genes to return per PC. Used to avoid genes from one PC dominating the entire analysis.                   |

# Value

A vector of genes whose p-values are statistically significant for at least one of the given PCs.

#### See Also

ProjectDim JackStraw

PercentAbove 143

#### **Examples**

```
data("pbmc_small")
PCASigGenes(pbmc_small, pcs.use = 1:2)
```

PercentAbove

Calculate the percentage of a vector above some threshold

#### **Description**

Calculate the percentage of a vector above some threshold

#### Usage

```
PercentAbove(x, threshold)
```

## **Arguments**

x Vector of values

threshold Threshold to use when calculating percentage

#### Value

Returns the percentage of x values above the given threshold

## **Examples**

```
set.seed(42)
PercentAbove(sample(1:100, 10), 75)
```

PercentageFeatureSet

Calculate the percentage of all counts that belong to a given set of features

## **Description**

This function enables you to easily calculate the percentage of all the counts belonging to a subset of the possible features for each cell. This is useful when trying to compute the percentage of transcripts that map to mitochondrial genes for example. The calculation here is simply the column sum of the matrix present in the counts slot for features belonging to the set divided by the column sum for all features times 100.

144 PlotClusterTree

#### Usage

```
PercentageFeatureSet(
  object,
  pattern = NULL,
  features = NULL,
  col.name = NULL,
  assay = NULL
)
```

#### **Arguments**

object A Seurat object

pattern A regex pattern to match features against

features A defined feature set. If features provided, will ignore the pattern matching

col.name Name in meta.data column to assign. If this is not null, returns a Seurat object

with the proportion of the feature set stored in metadata.

assay Assay to use

#### Value

Returns a vector with the proportion of the feature set or if md.name is set, returns a Seurat object with the proportion of the feature set stored in metadata.

## **Examples**

```
data("pbmc_small")
# Calculate the proportion of transcripts mapping to mitochondrial genes
# NOTE: The pattern provided works for human gene names. You may need to adjust depending on your
# system of interest
pbmc_small[["percent.mt"]] <- PercentageFeatureSet(object = pbmc_small, pattern = "^MT-")</pre>
```

PlotClusterTree

Plot clusters as a tree

# **Description**

Plots previously computed tree (from BuildClusterTree)

```
PlotClusterTree(object, direction = "downwards", ...)
```

PlotPerturbScore 145

## Arguments

```
object Seurat object

direction A character string specifying the direction of the tree (default is downwards)
Possible options: "rightwards", "leftwards", "upwards", and "downwards".

Additional arguments to ape::plot.phylo
```

### Value

Plots dendogram (must be precomputed using BuildClusterTree), returns no value

#### **Examples**

```
if (requireNamespace("ape", quietly = TRUE)) {
  data("pbmc_small")
  pbmc_small <- BuildClusterTree(object = pbmc_small)
  PlotClusterTree(object = pbmc_small)
}</pre>
```

PlotPerturbScore

Function to plot perturbation score distributions.

## **Description**

Density plots to visualize perturbation scores calculated from RunMixscape function.

### Usage

```
PlotPerturbScore(
  object,
  target.gene.class = "gene",
  target.gene.ident = NULL,
  mixscape.class = "mixscape_class",
  col = "orange2",
  split.by = NULL,
  before.mixscape = FALSE,
  prtb.type = "KO"
)
```

## **Arguments**

```
object An object of class Seurat.

target.gene.class

meta data column specifying all target gene names in the experiment.

target.gene.ident

Target gene name to visualize perturbation scores for.

mixscape.class meta data column specifying mixscape classifications.
```

146 PolyDimPlot

Specify color of target gene class or knockout cell class. For control non-targeting and non-perturbed cells, colors are set to different shades of grey.

Split.by For datasets with more than one cell type. Set equal TRUE to visualize perturbation scores for each cell type separately.

before.mixscape

Option to split densities based on mixscape classification (default) or original target gene classification. Default is set to NULL and plots cells by original class ID.

prtb.type specify type of CRISPR perturbation expected for labeling mixscape classifica-

tions. Default is KO.

### Value

A ggplot object.

PolyDimPlot Polygon DimPlot

### Description

Plot cells as polygons, rather than single points. Color cells by identity, or a categorical variable in metadata

# Usage

```
PolyDimPlot(
  object,
  group.by = NULL,
  cells = NULL,
  poly.data = "spatial",
  flip.coords = FALSE
)
```

# **Arguments**

object Seurat object
group.by A grouping variable present in the metadata. Default is to use the groupings present in the current cell identities (Idents(object = object))

cells Vector of cells to plot (default is all cells)

poly.data Name of the polygon dataframe in the misc slot

flip.coords Flip x and y coordinates

#### Value

Returns a ggplot object

PolyFeaturePlot 147

### Description

Plot cells as polygons, rather than single points. Color cells by any value accessible by FetchData.

## Usage

```
PolyFeaturePlot(
  object,
  features,
  cells = NULL,
  poly.data = "spatial",
  ncol = ceiling(x = length(x = features)/2),
  min.cutoff = 0,
  max.cutoff = NA,
  common.scale = TRUE,
  flip.coords = FALSE
)
```

### **Arguments**

object Seurat object features Vector of features to plot. Features can come from: • An Assay feature (e.g. a gene name - "MS4A1") • A column name from meta.data (e.g. mitochondrial percentage - "percent.mito") • A column name from a DimReduc object corresponding to the cell embedding values (e.g. the PC 1 scores - "PC\_1") cells Vector of cells to plot (default is all cells) Name of the polygon dataframe in the misc slot poly.data ncol Number of columns to split the plot into min.cutoff, max.cutoff Vector of minimum and maximum cutoff values for each feature, may specify quantile in the form of 'q##' where '##' is the quantile (eg, 'q1', 'q10') common.scale Flip x and y coordinates flip.coords

## Value

Returns a ggplot object

148 PredictAssay

PredictAssay

Predict value from nearest neighbors

## **Description**

This function will predict expression or cell embeddings from its k nearest neighbors index. For each cell, it will average its k neighbors value to get its new imputed value. It can average expression value in assays and cell embeddings from dimensional reductions.

## Usage

```
PredictAssay(
  object,
  nn.idx,
  assay,
  reduction = NULL,
  dims = NULL,
  return.assay = TRUE,
  slot = "scale.data",
  features = NULL,
  mean.function = rowMeans,
  seed = 4273,
  verbose = TRUE
)
```

### **Arguments**

object The object used to calculate knn

nn.idx k near neighbour indices. A cells x k matrix.

assay Assay used for prediction

reduction Cell embedding of the reduction used for prediction

dims Number of dimensions of cell embedding return.assay Return an assay or a predicted matrix

slot slot used for prediction features features used for prediction

mean.function the function used to calculate row mean

seed Sets the random seed to check if the nearest neighbor is query cell

verbose Print progress

### Value

return an assay containing predicted expression value in the data slot

PrepLDA 149

| D | 2   | nl  | .DA |
|---|-----|-----|-----|
| г | rei | ונו | 111 |

Function to prepare data for Linear Discriminant Analysis.

# Description

This function performs unsupervised PCA on each mixscape class separately and projects each subspace onto all cells in the data.

# Usage

```
PrepLDA(
  object,
  de.assay = "RNA",
  pc.assay = "PRTB",
  labels = "gene",
  nt.label = "NT",
  npcs = 10,
  verbose = TRUE,
  logfc.threshold = 0.25
)
```

## **Arguments**

| object          | An object of class Seurat.                              |  |
|-----------------|---------------------------------------------------------|--|
| de.assay        | Assay to use for selection of DE genes.                 |  |
| pc.assay        | Assay to use for running Principle components analysis. |  |
| labels          | Meta data column with target gene class labels.         |  |
| nt.label        | Name of non-targeting cell class.                       |  |
| npcs            | Number of principle components to use.                  |  |
| verbose         | Print progress bar.                                     |  |
| logfc.threshold |                                                         |  |

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

### Value

Returns a list of the first 10 PCs from each projection.

150 PrepSCTFindMarkers

PrepSCTFindMarkers Prepare object to run differential expression on SCT assay with multiple models

## **Description**

Given a merged object with multiple SCT models, this function uses minimum of the median UMI (calculated using the raw UMI counts) of individual objects to reverse the individual SCT regression model using minimum of median UMI as the sequencing depth covariate. The counts slot of the SCT assay is replaced with recorrected counts and the data slot is replaced with log1p of recorrected counts.

## Usage

```
PrepSCTFindMarkers(object, assay = "SCT", verbose = TRUE)
```

### **Arguments**

| object  | Seurat object with SCT assays                                 |
|---------|---------------------------------------------------------------|
| assay   | Assay name where for SCT objects are stored; Default is 'SCT' |
| verbose | Print messages and progress                                   |

## Value

Returns a Seurat object with recorrected counts and data in the SCT assay.

### **Examples**

```
data("pbmc_small")
pbmc_small1 <- SCTransform(object = pbmc_small, variable.features.n = 20)</pre>
pbmc_small2 <- SCTransform(object = pbmc_small, variable.features.n = 20)</pre>
pbmc_merged <- merge(x = pbmc_small1, y = pbmc_small2)</pre>
pbmc_merged <- PrepSCTFindMarkers(object = pbmc_merged)</pre>
markers <- FindMarkers(</pre>
  object = pbmc_merged,
  ident.1 = "0",
  ident.2 = "1"
  assay = "SCT"
pbmc_subset <- subset(pbmc_merged, idents = c("0", "1"))</pre>
markers_subset <- FindMarkers(</pre>
  object = pbmc_subset,
  ident.1 = "0",
  ident.2 = "1",
  assay = "SCT",
  recorrect_umi = FALSE
)
```

151 **PrepSCTIntegration** 

PrepSCTIntegration

Prepare an object list normalized with sctransform for integration.

## **Description**

This function takes in a list of objects that have been normalized with the SCTransform method and performs the following steps:

- If anchor.features is a numeric value, calls SelectIntegrationFeatures to determine the features to use in the downstream integration procedure.
- Ensures that the sctransform residuals for the features specified to anchor features are present in each object in the list. This is necessary because the default behavior of SCTransform is to only store the residuals for the features determined to be variable. Residuals are recomputed for missing features using the stored model parameters via the GetResidual function.
- Subsets the scale.data slot to only contain the residuals for anchor.features for efficiency in downstream processing.

#### Usage

```
PrepSCTIntegration(
  object.list,
  assay = NULL,
  anchor.features = 2000,
  sct.clip.range = NULL,
  verbose = TRUE
)
```

### **Arguments**

object.list

A list of Seurat objects to prepare for integration

assay

The name of the Assay to use for integration. This can be a single name if all the assays to be integrated have the same name, or a character vector containing the name of each Assay in each object to be integrated. The specified assays must have been normalized using SCTransform. If NULL (default), the current default assay for each object is used.

anchor.features

Can be either:

- A numeric value. This will call SelectIntegrationFeatures to select the provided number of features to be used in anchor finding
- A vector of features to be used as input to the anchor finding process

sct.clip.range Numeric of length two specifying the min and max values the Pearson residual will be clipped to

verbose

Display output/messages

152 ProjectDim

#### Value

A list of Seurat objects with the appropriate scale. data slots containing only the required anchor. features.

### **Examples**

```
# to install the SeuratData package see https://github.com/satijalab/seurat-data
library(SeuratData)
data("panc8")
# panc8 is a merged Seurat object containing 8 separate pancreas datasets
# split the object by dataset and take the first 2 to integrate
pancreas.list <- SplitObject(panc8, split.by = "tech")[1:2]</pre>
# perform SCTransform normalization
pancreas.list <- lapply(X = pancreas.list, FUN = SCTransform)</pre>
# select integration features and prep step
features <- SelectIntegrationFeatures(pancreas.list)</pre>
pancreas.list <- PrepSCTIntegration(</pre>
  pancreas.list,
  anchor.features = features
)
# downstream integration steps
anchors <- FindIntegrationAnchors(</pre>
  pancreas.list.
  normalization.method = "SCT",
  anchor.features = features
pancreas.integrated <- IntegrateData(anchors, normalization.method = "SCT")</pre>
## End(Not run)
```

ProjectDim

Project Dimensional reduction onto full dataset

### Description

Takes a pre-computed dimensional reduction (typically calculated on a subset of genes) and projects this onto the entire dataset (all genes). Note that the cell loadings will remain unchanged, but now there are gene loadings for all genes.

```
ProjectDim(
  object,
  reduction = "pca",
```

ProjectUMAP 153

```
assay = NULL,
dims.print = 1:5,
nfeatures.print = 20,
overwrite = FALSE,
do.center = FALSE,
verbose = TRUE
)
```

## Arguments

object Seurat object
reduction Reduction to use
assay Assay to use
dims.print Number of dims to print features for
nfeatures.print
Number of features with highest/lowest loadings to print for each dimension
overwrite Replace the existing data in feature.loadings

do.center Center the dataset prior to projection (should be set to TRUE)
verbose Print top genes associated with the projected dimensions

### Value

Returns Seurat object with the projected values

### **Examples**

```
data("pbmc_small")
pbmc_small
pbmc_small <- ProjectDim(object = pbmc_small, reduction = "pca")
# Vizualize top projected genes in heatmap
DimHeatmap(object = pbmc_small, reduction = "pca", dims = 1, balanced = TRUE)</pre>
```

ProjectUMAP

Project query into UMAP coordinates of a reference

#### **Description**

This function will take a query dataset and project it into the coordinates of a provided reference UMAP. This is essentially a wrapper around two steps:

- FindNeighbors Find the nearest reference cell neighbors and their distances for each query
- RunUMAP Perform umap projection by providing the neighbor set calculated above and the umap model previously computed in the reference.

154 ProjectUMAP

```
ProjectUMAP(query, ...)
## Default S3 method:
ProjectUMAP(
  query,
  query.dims = NULL,
  reference,
  reference.dims = NULL,
  k.param = 30,
  nn.method = "annoy",
  n.trees = 50,
  annoy.metric = "cosine",
  12.norm = FALSE,
  cache.index = TRUE,
  index = NULL,
  neighbor.name = "query_ref.nn",
  reduction.model,
)
## S3 method for class 'DimReduc'
ProjectUMAP(
  query,
  query.dims = NULL,
  reference,
  reference.dims = NULL,
  k.param = 30,
  nn.method = "annoy",
  n.trees = 50,
  annoy.metric = "cosine",
  12.norm = FALSE,
  cache.index = TRUE,
  index = NULL,
  neighbor.name = "query_ref.nn",
  reduction.model,
)
## S3 method for class 'Seurat'
ProjectUMAP(
  query,
  query.reduction,
  query.dims = NULL,
  reference,
  reference.reduction,
  reference.dims = NULL,
  k.param = 30,
```

ProjectUMAP 155

```
nn.method = "annoy",
n.trees = 50,
annoy.metric = "cosine",
12.norm = FALSE,
cache.index = TRUE,
index = NULL,
neighbor.name = "query_ref.nn",
reduction.model,
reduction.name = "ref.umap",
reduction.key = "refUMAP_",
...
)
```

### **Arguments**

reduction.key

Query dataset query Additional parameters to RunUMAP query.dims Dimensions (columns) to use from query reference Reference dataset reference.dims Dimensions (columns) to use from reference k.param Defines k for the k-nearest neighbor algorithm Method for nearest neighbor finding. Options include: rann, annoy nn.method n.trees More trees gives higher precision when using annoy approximate nearest neighbor search annoy.metric Distance metric for annoy. Options include: euclidean, cosine, manhattan, and hamming 12.norm Take L2Norm of the data cache.index Include cached index in returned Neighbor object (only relevant if return.neighbor = TRUE)index Precomputed index. Useful if querying new data against existing index to avoid recomputing. neighbor.name Name to store neighbor information in the query reduction.model DimReduc object that contains the umap model query.reduction Name of reduction to use from the query for neighbor finding reference.reduction Name of reduction to use from the reference for neighbor finding reduction.name Name of projected UMAP to store in the query

Value for the projected UMAP key

156 Read10X

Radius.SlideSeq

Get Spot Radius

## **Description**

Get Spot Radius

## Usage

```
## S3 method for class 'SlideSeq'
Radius(object)

## S3 method for class 'STARmap'
Radius(object)

## S3 method for class 'VisiumV1'
Radius(object)
```

# Arguments

object

An image object

## See Also

```
SeuratObject::Radius
```

Read10X

Load in data from 10X

## **Description**

Enables easy loading of sparse data matrices provided by 10X genomics.

```
Read10X(
  data.dir,
  gene.column = 2,
  cell.column = 1,
  unique.features = TRUE,
  strip.suffix = FALSE
)
```

Read10X\_h5

## **Arguments**

data.dir

Directory containing the matrix.mtx, genes.tsv (or features.tsv), and barcodes.tsv files provided by 10X. A vector or named vector can be given in order to load several data directories. If a named vector is given, the cell barcode names will be prefixed with the name.

Specify which column of genes.tsv or features.tsv to use for gene names; default is 2

cell.column

Specify which column of barcodes.tsv to use for cell names; default is 1

unique.features

Make feature names unique (default TRUE)

strip.suffix

Remove trailing "-1" if present in all cell barcodes.

#### Value

If features.csv indicates the data has multiple data types, a list containing a sparse matrix of the data from each type will be returned. Otherwise a sparse matrix containing the expression data will be returned.

### **Examples**

```
## Not run:
# For output from CellRanger < 3.0
data_dir <- 'path/to/data/directory'
list.files(data_dir) # Should show barcodes.tsv, genes.tsv, and matrix.mtx
expression_matrix <- Read10X(data.dir = data_dir)
seurat_object = CreateSeuratObject(counts = expression_matrix)

# For output from CellRanger >= 3.0 with multiple data types
data_dir <- 'path/to/data/directory'
list.files(data_dir) # Should show barcodes.tsv.gz, features.tsv.gz, and matrix.mtx.gz
data <- Read10X(data.dir = data_dir)
seurat_object = CreateSeuratObject(counts = data$`Gene Expression`)
seurat_object[['Protein']] = CreateAssayObject(counts = data$`Antibody Capture`)

## End(Not run)</pre>
```

Read10X\_h5

Read 10X hdf5 file

# Description

Read count matrix from 10X CellRanger hdf5 file. This can be used to read both scATAC-seq and scRNA-seq matrices.

```
Read10X_h5(filename, use.names = TRUE, unique.features = TRUE)
```

158 Read10X\_Image

## **Arguments**

filename Path to h5 file
use.names Label row names with feature names rather than ID numbers.

unique.features

Make feature names unique (default TRUE)

## Value

Returns a sparse matrix with rows and columns labeled. If multiple genomes are present, returns a list of sparse matrices (one per genome).

Read10X\_Image

Load a 10X Genomics Visium Image

## **Description**

Load a 10X Genomics Visium Image

### Usage

```
Read10X_Image(
  image.dir,
  image.name = "tissue_lowres_image.png",
  filter.matrix = TRUE,
  ...
)
```

# Arguments

image.dir Path to directory with 10X Genomics visium image data; should include files

tissue\_lowres\_image.png,

image.name The file name of the image. Defaults to tissue\_lowres\_image.png. scalefactors\_json.json

and tissue\_positions\_list.csv

filter.matrix Filter spot/feature matrix to only include spots that have been determined to be

over tissue.

... Ignored for now

### Value

A VisiumV1 object

#### See Also

VisiumV1 Load10X\_Spatial

ReadAkoya 159

ReadAkoya

Read and Load Akoya CODEX data

# Description

Read and Load Akoya CODEX data

## Usage

```
ReadAkoya(
  filename,
  type = c("inform", "processor", "qupath"),
  filter = "DAPI|Blank|Empty",
  inform.quant = c("mean", "total", "min", "max", "std")
)

LoadAkoya(
  filename,
  type = c("inform", "processor", "qupath"),
  fov,
  assay = "Akoya",
  ...
)
```

## **Arguments**

| filename     | Path to matrix generated by upstream processing.                   |  |  |
|--------------|--------------------------------------------------------------------|--|--|
| type         | Specify which type matrix is being provided.                       |  |  |
|              | • "processor": matrix generated by CODEX Processor                 |  |  |
|              | <ul> <li>"inform": matrix generated by inForm</li> </ul>           |  |  |
|              | <ul> <li>"qupath": matrix generated by QuPath</li> </ul>           |  |  |
| filter       | A pattern to filter features by; pass NA to skip feature filtering |  |  |
| inform.quant | When type is "inform", the quantification level to read in         |  |  |
| fov          | Name to store FOV as                                               |  |  |
| assay        | Name to store expression matrix as                                 |  |  |
|              | Arguments passed on to ReadAkoya                                   |  |  |

## Value

ReadAkoya: A list with some combination of the following values

- "matrix": a sparse matrix with expression data; cells are columns and features are rows
- $\bullet$  "centroids": a data frame with cell centroid coordinates in three columns: "x", "y", and "cell"

160 ReadMtx

• "metadata": a data frame with cell-level meta data; includes all columns in filename that aren't in "matrix" or "centroids"

When type is "inform", additional expression matrices are returned and named using their segmentation type (eg. "nucleus", "membrane"). The "Entire Cell" segmentation type is returned in the "matrix" entry of the list

```
LoadAkoya: A Seurat object
```

## **Progress Updates with progressr**

This function uses **progressr** to render status updates and progress bars. To enable progress updates, wrap the function call in with\_progress or run handlers(global = TRUE) before running this function. For more details about **progressr**, please read vignette("progressr-intro")

#### Note

This function requires the data.table package to be installed

ReadMtx

Load in data from remote or local mtx files

## **Description**

Enables easy loading of sparse data matrices

## Usage

```
ReadMtx(
  mtx,
  cells,
  features,
  cell.column = 1,
  feature.column = 2,
  cell.sep = "\t",
  feature.sep = "\t",
  skip.cell = 0,
  skip.feature = 0,
  mtx.transpose = FALSE,
  unique.features = TRUE,
  strip.suffix = FALSE
)
```

# Arguments

mtx Name or remote URL of the mtx file

cells Name or remote URL of the cells/barcodes file features Name or remote URL of the features/genes file

ReadNanostring 161

| cell.column     | Specify which column of cells file to use for cell names; default is 1             |  |  |
|-----------------|------------------------------------------------------------------------------------|--|--|
| feature.column  | Specify which column of features files to use for feature/gene names; default is 2 |  |  |
| cell.sep        | Specify the delimiter in the cell name file                                        |  |  |
| feature.sep     | Specify the delimiter in the feature name file                                     |  |  |
| skip.cell       | Number of lines to skip in the cells file before beginning to read cell names      |  |  |
| skip.feature    | Number of lines to skip in the features file before beginning to gene names        |  |  |
| mtx.transpose   | Transpose the matrix after reading in                                              |  |  |
| unique.features |                                                                                    |  |  |
|                 | Make feature names unique (default TRUE)                                           |  |  |
| strip.suffix    | Remove trailing "-1" if present in all cell barcodes.                              |  |  |

## Value

A sparse matrix containing the expression data.

# **Examples**

```
## Not run:
# For local files:

expression_matrix <- ReadMtx(
    mtx = "count_matrix.mtx.gz", features = "features.tsv.gz",
    cells = "barcodes.tsv.gz"
)
seurat_object <- CreateSeuratObject(counts = expression_matrix)

# For remote files:

expression_matrix <- ReadMtx(mtx = "http://localhost/matrix.mtx",
    cells = "http://localhost/barcodes.tsv",
    features = "http://localhost/genes.tsv")
seurat_object <- CreateSeuratObject(counts = data)

## End(Not run)</pre>
```

 ${\it ReadNanostring}$ 

Read and Load Nanostring SMI data

## **Description**

Read and Load Nanostring SMI data

162 ReadNanostring

```
ReadNanostring(
      data.dir,
      mtx.file = NULL,
      metadata.file = NULL,
      molecules.file = NULL,
      segmentations.file = NULL,
      type = "centroids"
      mol.type = "pixels",
      metadata = NULL,
      mols.filter = NA_character_,
      genes.filter = NA_character_,
      fov.filter = NULL,
      subset.counts.matrix = NULL,
      cell.mols.only = TRUE
    )
    LoadNanostring(data.dir, fov, assay = "Nanostring")
Arguments
    data.dir
                     Path to folder containing Nanostring SMI outputs
    mtx.file
                     Path to Nanostring cell x gene matrix CSV
    metadata.file
                     Contains metadata including cell center, area, and stain intensities
    molecules.file Path to molecules file
    segmentations.file
                     Path to segmentations CSV
                     Type of cell spatial coordinate matrices to read; choose one or more of:
    type
                        • "centroids": cell centroids in pixel coordinate space
                        • "segmentations": cell segmentations in pixel coordinate space
                     Type of molecule spatial coordinate matrices to read; choose one or more of:
    mol.type
                        • "pixels": molecule coordinates in pixel space
    metadata
                     Type of available metadata to read; choose zero or more of:
                        • "Area": number of pixels in cell segmentation
                        · "fov": cell's fov
                        • "Mean.MembraneStain": mean membrane stain intensity
                        • "Mean.DAPI": mean DAPI stain intensity
                        • "Mean.G": mean green channel stain intensity
                        • "Mean.Y": mean yellow channel stain intensity
                        • "Mean.R": mean red channel stain intensity
                        • "Max.MembraneStain": max membrane stain intensity
                        • "Max.DAPI": max DAPI stain intensity
                        • "Max.G": max green channel stain intensity
                        • "Max.Y": max yellow stain intensity
```

ReadNanostring 163

• "Max.R": max red stain intensity

mols.filter Filter molecules that match provided string

genes.filter Filter genes from cell x gene matrix that match provided string

fov.filter Only load in select FOVs. Nanostring SMI data contains 30 total FOVs.

subset.counts.matrix

If the counts matrix should be built from molecule coordinates for a specific segmentation; One of:

• "Nuclear": nuclear segmentations

• "Cytoplasm": cell cytoplasm segmentations

• "Membrane": cell membrane segmentations

cell.mols.only If TRUE, only load molecules within a cell

fov Name to store FOV as

assay Name to store expression matrix as

#### Value

ReadNanostring: A list with some combination of the following values:

- "matrix": a sparse matrix with expression data; cells are columns and features are rows
- "centroids": a data frame with cell centroid coordinates in three columns: "x", "y", and "cell"
- "pixels": a data frame with molecule pixel coordinates in three columns: "x", "y", and "gene"

LoadNanostring: A Seurat object

### **Progress Updates with progressr**

This function uses **progressr** to render status updates and progress bars. To enable progress updates, wrap the function call in with\_progress or run handlers(global = TRUE) before running this function. For more details about **progressr**, please read vignette("progressr-intro")

#### Parallelization with future

This function uses **future** to enable parallelization. Parallelization strategies can be set using plan. Common plans include "sequential" for non-parallelized processing or "multisession" for parallel evaluation using multiple R sessions; for other plans, see the "Implemented evaluation strategies" section of ?future::plan. For a more thorough introduction to **future**, see vignette("future-1-overview")

#### Note

This function requires the **data.table** package to be installed

164 ReadSlideSeq

ReadParseBio

Read output from Parse Biosciences

# Description

Read output from Parse Biosciences

# Usage

```
ReadParseBio(data.dir, ...)
```

# Arguments

data.dir Directory containing the data files
... Extra parameters passed to ReadMtx

ReadSlideSeq

Load Slide-seq spatial data

# Description

Load Slide-seq spatial data

## Usage

```
ReadSlideSeq(coord.file, assay = "Spatial")
```

# **Arguments**

coord.file Path to csv file containing bead coordinate positions

assay Name of assay to associate image to

## Value

A SlideSeq object

## See Also

SlideSeq

ReadSTARsolo 165

ReadSTARsolo Read o

Read output from STARsolo

# Description

Read output from STARsolo

# Usage

```
ReadSTARsolo(data.dir, ...)
```

# Arguments

data.dir Directory containing the data files
... Extra parameters passed to ReadMtx

ReadVitessce

Read Data From Vitessce

## **Description**

Read in data from Vitessce-formatted JSON files

# Usage

```
ReadVitessce(
  counts = NULL,
  coords = NULL,
  molecules = NULL,
  type = c("segmentations", "centroids"),
  filter = NA_character_
)
LoadHuBMAPCODEX(data.dir, fov, assay = "CODEX")
```

# Arguments

| counts    | Path or URL to a Vitessce-formatted JSON file with expression data; should end in ".genes.json" or ".clusters.json"; pass NULL to skip |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| coords    | Path or URL to a Vitessce-formatted JSON file with cell/spot spatial coordinates; should end in ".cells.json"; pass NULL to skip       |
| molecules | Path or URL to a Vitessce-formatted JSON file with molecule spatial coordinates; should end in ".molecules.json"; pass NULL to skip    |
| type      | Type of cell/spot spatial coordinates to return, choose one or more from:                                                              |

166 ReadVitessce

| • | "segmentations" | cell/spot | segmentations |
|---|-----------------|-----------|---------------|
|---|-----------------|-----------|---------------|

• "centroids" cell/spot centroids

filter A character to filter molecules by, pass NA to skip molecule filtering data.dir Path to a directory containing Vitessce cells and clusters JSONs fov Name to store FOV as

Name to store expression matrix as

#### Value

ReadVitessce: A list with some combination of the following values:

- "counts": if counts is not NULL, an expression matrix with cells as columns and features as rows
- "centroids": if coords is not NULL and type is contains "centroids", a data frame with cell centroids in three columns: "x", "y", and "cell"
- "segmentations": if coords is not NULL and type contains "centroids", a data frame with cell segmentations in three columns: "x", "y" and "cell"
- "molecules": if molecules is not NULL, a data frame with molecule spatial coordinates in three columns: "x", "y", and "gene"

LoadHuBMAPCODEX: A Seurat object

### **Progress Updates with progressr**

This function uses **progressr** to render status updates and progress bars. To enable progress updates, wrap the function call in with\_progress or run handlers(global = TRUE) before running this function. For more details about **progressr**, please read vignette("progressr-intro")

### Note

This function requires the **jsonlite** package to be installed

## **Examples**

```
## Not run:
coords <- ReadVitessce(
    counts =
        "https://s3.amazonaws.com/vitessce-data/0.0.31/master_release/wang/wang.genes.json",
    coords =
        "https://s3.amazonaws.com/vitessce-data/0.0.31/master_release/wang/wang.cells.json",
    molecules =
        "https://s3.amazonaws.com/vitessce-data/0.0.31/master_release/wang/wang.molecules.json")
)
names(coords)
coords$counts[1:10, 1:10]
head(coords$centroids)
head(coords$segmentations)
head(coords$molecules)</pre>
```

ReadVizgen 167

```
## End(Not run)
```

ReadVizgen

Read and Load MERFISH Input from Vizgen

## Description

Read and load in MERFISH data from Vizgen-formatted files

# Usage

```
ReadVizgen(
  data.dir,
  transcripts = NULL,
  spatial = NULL,
  molecules = NULL,
  type = "segmentations",
  mol.type = "microns",
  metadata = NULL,
  filter = NA_character_,
  z = 3L
)
LoadVizgen(data.dir, fov, assay = "Vizgen", z = 3L)
```

### Arguments

data.dir

Path to the directory with Vizgen MERFISH files; requires at least one of the following files present:

- "cell\_by\_gene.csv": used for reading count matrix
- "cell\_metadata.csv": used for reading cell spatial coordinate matrices
- "detected\_transcripts.csv": used for reading molecule spatial coordinate matrices

transcripts

Optional file path for counts matrix; pass NA to suppress reading counts matrix

spatial

Optional file path for spatial metadata; pass NA to suppress reading spatial coordinates. If spatial is provided and type is "segmentations", uses dirname(spatial)

instead of data.dir to find HDF5 files

molecules

Optional file path for molecule coordinates file; pass NA to suppress reading spatial molecule information

type

Type of cell spatial coordinate matrices to read; choose one or more of:

- "segmentations": cell segmentation vertices; requires <a href="hdf5r">hdf5r</a> to be installed and requires a directory "cell\_boundaries" within data.dir. Within "cell\_boundaries", there must be one or more HDF5 file named "feature\_data\_##.hdf5"
- "centroids": cell centroids in micron coordinate space

168 ReadVizgen

|          | <ul> <li>"boxes": cell box outlines in micron coordinate space</li> </ul>    |
|----------|------------------------------------------------------------------------------|
| mol.type | Type of molecule spatial coordinate matrices to read; choose one or more of: |
|          | <ul> <li>"pixels": molecule coordinates in pixel space</li> </ul>            |
|          | • "microns": molecule coordinates in micron space                            |
| metadata | Type of available metadata to read; choose zero or more of:                  |
|          | "volume": estimated cell volume                                              |
|          | • "fov": cell's fov                                                          |
| filter   | A character to filter molecules by, pass NA to skip molecule filtering       |
| Z        | Z-index to load; must be between 0 and 6, inclusive                          |
| fov      | Name to store FOV as                                                         |
| assay    | Name to store expression matrix as                                           |

### Value

ReadVizgen: A list with some combination of the following values:

- "transcripts": a sparse matrix with expression data; cells are columns and features are rows
- "segmentations": a data frame with cell polygon outlines in three columns: "x", "y", and "cell"
- "centroids": a data frame with cell centroid coordinates in three columns: "x", "y", and "cell"
- "boxes": a data frame with cell box outlines in three columns: "x", "y", and "cell"
- "microns": a data frame with molecule micron coordinates in three columns: "x", "y", and "gene"
- "pixels": a data frame with molecule pixel coordinates in three columns: "x", "y", and "gene"
- "metadata": a data frame with the cell-level metadata requested by metadata

LoadVizgen: A Seurat object

### **Progress Updates with progressr**

This function uses **progressr** to render status updates and progress bars. To enable progress updates, wrap the function call in with\_progress or run handlers(global = TRUE) before running this function. For more details about **progressr**, please read vignette("progressr-intro")

#### Parallelization with future

This function uses **future** to enable parallelization. Parallelization strategies can be set using plan. Common plans include "sequential" for non-parallelized processing or "multisession" for parallel evaluation using multiple R sessions; for other plans, see the "Implemented evaluation strategies" section of ?future::plan. For a more thorough introduction to **future**, see vignette("future-1-overview")

#### Note

This function requires the **data.table** package to be installed

RegroupIdents 169

| $D_{\sim}$ | ~~  | $\sim$ | ·n | ΤА           | ~ n | ıts |
|------------|-----|--------|----|--------------|-----|-----|
| πe         | וצי | OL.    | w  | $_{\rm L}$ u | eı  | ıLS |

Regroup idents based on meta.data info

## Description

For cells in each ident, set a new identity based on the most common value of a specified metadata column.

## Usage

```
RegroupIdents(object, metadata)
```

### **Arguments**

object

Seurat object

metadata

Name of metadata column

### Value

A Seurat object with the active idents regrouped

### **Examples**

```
data("pbmc_small")
pbmc_small <- RegroupIdents(pbmc_small, metadata = "groups")</pre>
```

RelativeCounts

Normalize raw data to fractions

## Description

Normalize count data to relative counts per cell by dividing by the total per cell. Optionally use a scale factor, e.g. for counts per million (CPM) use scale.factor = 1e6.

## Usage

```
RelativeCounts(data, scale.factor = 1, verbose = TRUE)
```

## **Arguments**

data Matrix with the raw count data scale.factor Scale the result. Default is 1

verbose Print progress

## Value

Returns a matrix with the relative counts

## **Examples**

```
mat <- matrix(data = rbinom(n = 25, size = 5, prob = 0.2), nrow = 5)
mat
mat_norm <- RelativeCounts(data = mat)
mat_norm</pre>
```

RenameCells.SCTAssay Rename Cells in an Object

# Description

Rename Cells in an Object

## Usage

```
## S3 method for class 'SCTAssay'
RenameCells(object, new.names = NULL, ...)
## S3 method for class 'SlideSeq'
RenameCells(object, new.names = NULL, ...)
## S3 method for class 'STARmap'
RenameCells(object, new.names = NULL, ...)
## S3 method for class 'VisiumV1'
RenameCells(object, new.names = NULL, ...)
```

# **Arguments**

```
object An object

new.names vector of new cell names

... Arguments passed to other methods
```

### See Also

```
SeuratObject::RenameCells
```

RidgePlot 171

# Description

Draws a ridge plot of single cell data (gene expression, metrics, PC scores, etc.)

# Usage

```
RidgePlot(
  object,
  features,
  cols = NULL,
  idents = NULL,
  sort = FALSE,
  assay = NULL,
  group.by = NULL,
  y.max = NULL,
  same.y.lims = FALSE,
  log = FALSE,
  ncol = NULL,
  slot = "data",
  stack = FALSE,
  combine = TRUE,
  fill.by = "feature"
)
```

# Arguments

| object      | Seurat object                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| features    | Features to plot (gene expression, metrics, PC scores, anything that can be retreived by FetchData)                                                                |
| cols        | Colors to use for plotting                                                                                                                                         |
| idents      | Which classes to include in the plot (default is all)                                                                                                              |
| sort        | Sort identity classes (on the x-axis) by the average expression of the attribute being potted, can also pass 'increasing' or 'decreasing' to change sort direction |
| assay       | Name of assay to use, defaults to the active assay                                                                                                                 |
| group.by    | Group (color) cells in different ways (for example, orig.ident)                                                                                                    |
| y.max       | Maximum y axis value                                                                                                                                               |
| same.y.lims | Set all the y-axis limits to the same values                                                                                                                       |
| log         | plot the feature axis on log scale                                                                                                                                 |
| ncol        | Number of columns if multiple plots are displayed                                                                                                                  |
| slot        | Slot to pull expression data from (e.g. "counts" or "data")                                                                                                        |
|             |                                                                                                                                                                    |

172 RunCCA

| stack   | Horizontally stack plots for each feature                                                |
|---------|------------------------------------------------------------------------------------------|
| combine | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot |
| fill.by | Color violins/ridges based on either 'feature' or 'ident'                                |

## Value

A patchworked ggplot object if combine = TRUE; otherwise, a list of ggplot objects

## **Examples**

```
data("pbmc_small")
RidgePlot(object = pbmc_small, features = 'PC_1')
```

RunCCA

Perform Canonical Correlation Analysis

## **Description**

Runs a canonical correlation analysis using a diagonal implementation of CCA. For details about stored CCA calculation parameters, see PrintCCAParams.

```
RunCCA(object1, object2, ...)
## Default S3 method:
RunCCA(
 object1,
  object2,
  standardize = TRUE,
  num.cc = 20,
  seed.use = 42,
  verbose = FALSE,
)
## S3 method for class 'Seurat'
RunCCA(
  object1,
  object2,
  assay1 = NULL,
  assay2 = NULL,
  num.cc = 20,
  features = NULL,
  renormalize = FALSE,
```

RunCCA 173

```
rescale = FALSE,
compute.gene.loadings = TRUE,
add.cell.id1 = NULL,
add.cell.id2 = NULL,
verbose = TRUE,
...
)
```

# Arguments

| object1                    | First Seurat object                                                                                                                                         |  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| object2                    | Second Seurat object.                                                                                                                                       |  |
|                            | Extra parameters (passed onto MergeSeurat in case with two objects passed, passed onto ScaleData in case with single object and rescale.groups set to TRUE) |  |
| standardize                | Standardize matrices - scales columns to have unit variance and mean 0                                                                                      |  |
| num.cc                     | Number of canonical vectors to calculate                                                                                                                    |  |
| seed.use                   | Random seed to set. If NULL, does not set a seed                                                                                                            |  |
| verbose                    | Show progress messages                                                                                                                                      |  |
| assay1, assay2             | Assays to pull from in the first and second objects, respectively                                                                                           |  |
| features                   | Set of genes to use in CCA. Default is the union of both the variable features sets present in both objects.                                                |  |
| renormalize                | Renormalize raw data after merging the objects. If FALSE, merge the data matrices also.                                                                     |  |
| rescale                    | Rescale the datasets prior to CCA. If FALSE, uses existing data in the scale data slots.                                                                    |  |
| compute.gene.loadings      |                                                                                                                                                             |  |
|                            | Also compute the gene loadings. NOTE - this will scale every gene in the dataset which may impose a high memory cost.                                       |  |
| add.cell.id1, add.cell.id2 |                                                                                                                                                             |  |
|                            | Add                                                                                                                                                         |  |

## Value

Returns a combined Seurat object with the CCA results stored.

## See Also

```
merge.Seurat
```

# **Examples**

```
data("pbmc_small")
pbmc_small
# As CCA requires two datasets, we will split our test object into two just for this example
pbmc1 <- subset(pbmc_small, cells = colnames(pbmc_small)[1:40])
pbmc2 <- subset(pbmc_small, cells = colnames(x = pbmc_small)[41:80])</pre>
```

174 RunICA

```
pbmc1[["group"]] <- "group1"
pbmc2[["group"]] <- "group2"
pbmc_cca <- RunCCA(object1 = pbmc1, object2 = pbmc2)
# Print results
print(x = pbmc_cca[["cca"]])</pre>
```

RunICA

Run Independent Component Analysis on gene expression

## **Description**

Run fastica algorithm from the ica package for ICA dimensionality reduction. For details about stored ICA calculation parameters, see PrintICAParams.

```
RunICA(object, ...)
## Default S3 method:
RunICA(
  object,
  assay = NULL,
  nics = 50,
  rev.ica = FALSE,
  ica.function = "icafast",
  verbose = TRUE,
  ndims.print = 1:5,
  nfeatures.print = 30,
  reduction.name = "ica",
  reduction.key = "ica_",

## **Arguments**

features

| object          | Seurat object                                                                                                                                              |  |  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
|                 | Additional arguments to be passed to fastica                                                                                                               |  |  |
| assay           | Name of Assay ICA is being run on                                                                                                                          |  |  |
| nics            | Number of ICs to compute                                                                                                                                   |  |  |
| rev.ica         | By default, computes the dimensional reduction on the cell $x$ feature matrix. Setting to true will compute it on the transpose (feature $x$ cell matrix). |  |  |
| ica.function    | ICA function from ica package to run (options: icafast, icaimax, icajade)                                                                                  |  |  |
| verbose         | Print the top genes associated with high/low loadings for the ICs                                                                                          |  |  |
| ndims.print     | ICs to print genes for                                                                                                                                     |  |  |
| nfeatures.print |                                                                                                                                                            |  |  |
|                 | Number of genes to print for each IC                                                                                                                       |  |  |
| reduction.name  | dimensional reduction name                                                                                                                                 |  |  |
| reduction.key   | dimensional reduction key, specifies the string before the number for the dimension names.                                                                 |  |  |
| seed.use        | Set a random seed. Setting NULL will not set a seed.                                                                                                       |  |  |

Features to compute ICA on

176 RunLDA

RunLDA

Run Linear Discriminant Analysis

# Description

Run Linear Discriminant Analysis
Function to perform Linear Discriminant Analysis.

```
RunLDA(object, ...)
## Default S3 method:
RunLDA(
 object,
  labels,
  assay = NULL,
  verbose = TRUE,
  ndims.print = 1:5,
  nfeatures.print = 30,
  reduction.key = "LDA_",
  seed = 42,
)
## S3 method for class 'Assay'
RunLDA(
  object,
  assay = NULL,
  labels,
  features = NULL,
  verbose = TRUE,
  ndims.print = 1:5,
  nfeatures.print = 30,
  reduction.key = "LDA_",
  seed = 42,
)
## S3 method for class 'Seurat'
RunLDA(
  object,
  assay = NULL,
  labels,
  features = NULL,
  reduction.name = "lda",
```

RunMarkVario 177

```
reduction.key = "LDA_",
seed = 42,
verbose = TRUE,
ndims.print = 1:5,
nfeatures.print = 30,
...
)
```

## **Arguments**

object An object of class Seurat.

... Arguments passed to other methods

labels Meta data column with target gene class labels.

Assay to use for performing Linear Discriminant Analysis (LDA).

Verbose Print the top genes associated with high/low loadings for the PCs

ndims.print Number of LDA dimensions to print.

nfeatures.print

Number of features to print for each LDA component.

reduction.key Reduction key name.
seed Value for random seed

features Features to compute LDA on

reduction.name dimensional reduction name, lda by default

RunMarkVario Run the mark variogram computation on a given position matrix and

expression matrix.

## **Description**

Wraps the functionality of markvario from the spatstat package.

#### Usage

```
RunMarkVario(spatial.location, data, ...)
```

## **Arguments**

spatial.location

A 2 column matrix giving the spatial locations of each of the data points also in

data

data Matrix containing the data used as "marks" (e.g. gene expression)

... Arguments passed to markvario

178 RunMixscape

| RunMixscape | Run Mixscape |
|-------------|--------------|
|             |              |

# Description

Function to identify perturbed and non-perturbed gRNA expressing cells that accounts for multiple treatments/conditions/chemical perturbations.

# Usage

```
RunMixscape(
  object,
  assay = "PRTB",
  slot = "scale.data",
 labels = "gene",
nt.class.name = "NT",
  new.class.name = "mixscape_class",
 min.de.genes = 5,
 min.cells = 5,
  de.assay = "RNA",
  logfc.threshold = 0.25,
  iter.num = 10,
  verbose = FALSE,
  split.by = NULL,
  fine.mode = FALSE,
  fine.mode.labels = "guide_ID",
 prtb.type = "KO"
)
```

# Arguments

| object         | An object of class Seurat.                                                                                                                                  |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assay          | Assay to use for mixscape classification.                                                                                                                   |
| slot           | Assay data slot to use.                                                                                                                                     |
| labels         | metadata column with target gene labels.                                                                                                                    |
| nt.class.name  | Classification name of non-targeting gRNA cells.                                                                                                            |
| new.class.name | Name of mixscape classification to be stored in metadata.                                                                                                   |
| min.de.genes   | Required number of genes that are differentially expressed for method to separate perturbed and non-perturbed cells.                                        |
| min.cells      | Minimum number of cells in target gene class. If fewer than this many cells are assigned to a target gene class during classification, all are assigned NP. |
| de.assay       | Assay to use when performing differential expression analysis. Usually RNA.                                                                                 |

RunMoransI 179

logfc.threshold

Limit testing to genes which show, on average, at least X-fold difference (log-scale) between the two groups of cells. Default is 0.25 Increasing logfc.threshold speeds up the function, but can miss weaker signals.

iter.num Number of normalmixEM iterations to run if convergence does not occur.

verbose Display messages

split.by metadata column with experimental condition/cell type classification informa-

tion. This is meant to be used to account for cases a perturbation is condition/cell

type -specific.

fine.mode When this is equal to TRUE, DE genes for each target gene class will be calcu-

lated for each gRNA separately and pooled into one DE list for calculating the

perturbation score of every cell and their subsequent classification.

fine.mode.labels

metadata column with gRNA ID labels.

prtb.type specify type of CRISPR perturbation expected for labeling mixscape classifica-

tions. Default is KO.

#### Value

Returns Seurat object with with the following information in the meta data and tools slots:

**mixscape\_class** Classification result with cells being either classified as perturbed (KO, by default) or non-perturbed (NP) based on their target gene class.

mixscape\_class.global Global classification result (perturbed, NP or NT)

**p\_ko** Posterior probabilities used to determine if a cell is KO (default). Name of this item will change to match prtb.type parameter setting. (>0.5) or NP

**perturbation score** Perturbation scores for every cell calculated in the first iteration of the function.

RunMoransI

Compute Moran's I value.

### **Description**

Wraps the functionality of the Moran.I function from the ape package. Weights are computed as 1/distance.

#### Usage

RunMoransI(data, pos, verbose = TRUE)

#### **Arguments**

data Expression matrix pos Position matrix

verbose Display messages/progress

180 RunPCA

RunPCA

Run Principal Component Analysis

### **Description**

Run a PCA dimensionality reduction. For details about stored PCA calculation parameters, see PrintPCAParams.

```
RunPCA(object, ...)
## Default S3 method:
RunPCA(
  object,
  assay = NULL,
 npcs = 50,

|                                                                            | Features to compute PCA on. If features=NULL, PCA will be run usi variable features for the Assay. Note that the features must be present scaled data. Any requested features that are not scaled or have 0 variance be dropped, and the PCA will be run using the remaining features. |                                                                                                                   |  |
|                                                                            | reduction.name                                                                                                                                                                                                                                                                         | dimensional reduction name, pca by default                                                                        |  |
|                                                                            |                                                                                                                                                                                                                                                                                        |                                                                                                                   |  |

## Value

Returns Seurat object with the PCA calculation stored in the reductions slot

182 RunSLSI

RunSLSI

Run Supervised Latent Semantic Indexing

### **Description**

Run a supervised LSI (SLSI) dimensionality reduction supervised by a cell-cell kernel. SLSI is used to capture a linear transformation of peaks that maximizes its dependency to the given cell-cell kernel.

```
RunSLSI(object, ...)
## Default S3 method:
RunSLSI(
 object,
  assay = NULL,
  n = 50,
  reduction.key = "SLSI_",
  graph = NULL,
  verbose = TRUE,
  seed.use = 42,
)
## S3 method for class 'Assay'
RunSLSI(
 object,
  assay = NULL,
  features = NULL,
  n = 50,
  reduction.key = "SLSI_",
  graph = NULL,
  verbose = TRUE,
  seed.use = 42,
)
## S3 method for class 'Seurat'
RunSLSI(
  object,
  assay = NULL,
  features = NULL,
  n = 50,
  reduction.name = "slsi",
  reduction.key = "SLSI_",
  graph = NULL,
```

RunSPCA 183

```
verbose = TRUE,
seed.use = 42,
...
)
```

#### **Arguments**

object An object
... Arguments passed to IRLBA irlba
assay Name of Assay SLSI is being run on
n Total Number of SLSI components to compute and store
reduction.key dimensional reduction key, specifies the string before the number for the dimension names
graph Graph used supervised by SLSI
verbose Display messages

seed. use Set a random seed. Setting NULL will not set a seed.

features Features to compute SLSI on. If NULL, SLSI will be run using the variable

features for the Assay.

reduction.name dimensional reduction name

#### Value

Returns Seurat object with the SLSI calculation stored in the reductions slot

RunSPCA

Run Supervised Principal Component Analysis

#### **Description**

Run a supervised PCA (SPCA) dimensionality reduction supervised by a cell-cell kernel. SPCA is used to capture a linear transformation which maximizes its dependency to the given cell-cell kernel. We use SNN graph as the kernel to supervise the linear matrix factorization.

```
RunSPCA(object, ...)
## Default S3 method:
RunSPCA(
  object,
  assay = NULL,
  npcs = 50,
  reduction.key = "SPC_",
  graph = NULL,
  verbose = FALSE,
```

184 RunSPCA

```
seed.use = 42,
)
## S3 method for class 'Assay'
RunSPCA(
 object,
  assay = NULL,
  features = NULL,
  npcs = 50,
  reduction.key = "SPC_",
  graph = NULL,
  verbose = TRUE,
  seed.use = 42,
)
## S3 method for class 'Seurat'
RunSPCA(
  object,
  assay = NULL,
  features = NULL,
  npcs = 50,
  reduction.name = "spca",
  reduction.key = "SPC_",
  graph = NULL,
  verbose = TRUE,
  seed.use = 42,
)
```

### Arguments

| object | An object |
|--------|-----------|
|        |           |

... Arguments passed to other methods and IRLBA

assay Name of Assay SPCA is being run on

npcs Total Number of SPCs to compute and store (50 by default)

reduction.key dimensional reduction key, specifies the string before the number for the dimen-

sion names. SPC by default

graph Graph used supervised by SPCA

verbose Print the top genes associated with high/low loadings for the SPCs

seed.use Set a random seed. By default, sets the seed to 42. Setting NULL will not set a

seed.

features Features to compute SPCA on. If features=NULL, SPCA will be run using the

variable features for the Assay.

reduction.name dimensional reduction name, spca by default

RunTSNE 185

#### Value

Returns Seurat object with the SPCA calculation stored in the reductions slot

**RunTSNE** 

Run t-distributed Stochastic Neighbor Embedding

### **Description**

Run t-SNE dimensionality reduction on selected features. Has the option of running in a reduced dimensional space (i.e. spectral tSNE, recommended), or running based on a set of genes. For details about stored TSNE calculation parameters, see PrintTSNEParams.

```
RunTSNE(object, ...)
## S3 method for class 'matrix'
RunTSNE(
  object,
  assay = NULL,
  seed.use = 1,
  tsne.method = "Rtsne",
  dim.embed = 2,
  reduction.key = "tSNE_",
)
## S3 method for class 'DimReduc'
RunTSNE(
  object,
  cells = NULL,
  dims = 1:5,
  seed.use = 1,
  tsne.method = "Rtsne",
  dim.embed = 2,
  reduction.key = "tSNE_",
)
## S3 method for class 'dist'
```

RunTSNE

```
RunTSNE(
 object,
 assay = NULL,
  seed.use = 1,
 tsne.method = "Rtsne",
 dim.embed = 2,
 reduction.key = "tSNE_",
)
## S3 method for class 'Seurat'
RunTSNE(
 object,
 reduction = "pca",
 cells = NULL,
 dims = 1:5,
 features = NULL,
  seed.use = 1,
  tsne.method = "Rtsne",
 dim.embed = 2,
 distance.matrix = NULL,
 reduction.name = "tsne",
 reduction.key = "tSNE_",
)
```

# Arguments

| object        | Seurat object                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| •••           | Arguments passed to other methods and to t-SNE call (most commonly used is perplexity)                                                  |
| assay         | Name of assay that that t-SNE is being run on                                                                                           |
| seed.use      | Random seed for the t-SNE. If NULL, does not set the seed                                                                               |
| tsne.method   | Select the method to use to compute the tSNE. Available methods are:                                                                    |
|               | • Rtsne: Use the Rtsne package Barnes-Hut implementation of tSNE (default)                                                              |
|               | • FIt-SNE: Use the FFT-accelerated Interpolation-based t-SNE. Based on Kluger Lab code found here: https://github.com/KlugerLab/FIt-SNE |
| dim.embed     | The dimensional space of the resulting tSNE embedding (default is 2). For example, set to 3 for a 3d tSNE                               |
| reduction.key | dimensional reduction key, specifies the string before the number for the dimension names. tSNE_ by default                             |
| cells         | Which cells to analyze (default, all cells)                                                                                             |
| dims          | Which dimensions to use as input features                                                                                               |
| reduction     | Which dimensional reduction (e.g. PCA, ICA) to use for the tSNE. Default is PCA                                                         |

features If set, run the tSNE on this subset of features (instead of running on a set of reduced dimensions). Not set (NULL) by default; dims must be NULL to run on features distance.matrix

If set, runs tSNE on the given distance matrix instead of data matrix (experimental)

reduction.name dimensional reduction name, specifies the position in the object\$dr list. tsne by default

RunUMAP

Run UMAP

### **Description**

Runs the Uniform Manifold Approximation and Projection (UMAP) dimensional reduction technique. To run using umap.method="umap-learn", you must first install the umap-learn python package (e.g. via pip install umap-learn). Details on this package can be found here: https://github.com/lmcinnes/umap. For a more in depth discussion of the mathematics underlying UMAP, see the ArXiv paper here: https://arxiv.org/abs/1802.03426.

```
RunUMAP(object, ...)
## Default S3 method:
RunUMAP(
  object,
  reduction.key = "UMAP_",
  assay = NULL,
  reduction.model = NULL,

)
```

### **Arguments**

object An object Arguments passed to other methods and UMAP reduction.key dimensional reduction key, specifies the string before the number for the dimension names. UMAP by default assay Assay to pull data for when using features, or assay used to construct Graph if running UMAP on a Graph reduction.model DimReduc object that contains the umap model whether UMAP will return the uwot model return.model umap.method UMAP implementation to run. Can be uwot: Runs umap via the uwot R package uwot-learn: Runs umap via the uwot R package and return the learned umap umap-learn: Run the Seurat wrapper of the python umap-learn package

n.neighbors This determines the number of neighboring points used in local approximations

of manifold structure. Larger values will result in more global structure being preserved at the loss of detailed local structure. In general this parameter should

often be in the range 5 to 50.

n.components The dimension of the space to embed into.

metric metric: This determines the choice of metric used to measure distance in the input space. A wide variety of metrics are already coded, and a user defined

function can be passed as long as it has been JITd by numba.

n . epochs he number of training epochs to be used in optimizing the low dimensional em-

bedding. Larger values result in more accurate embeddings. If NULL is specified, a value will be selected based on the size of the input dataset (200 for large

datasets, 500 for small).

learning.rate The initial learning rate for the embedding optimization.

min.dist This controls how tightly the embedding is allowed compress points together.

Larger values ensure embedded points are more evenly distributed, while smaller values allow the algorithm to optimise more accurately with regard to local

structure. Sensible values are in the range 0.001 to 0.5.

spread The effective scale of embedded points. In combination with min.dist this de-

termines how clustered/clumped the embedded points are.

set.op.mix.ratio

Interpolate between (fuzzy) union and intersection as the set operation used to combine local fuzzy simplicial sets to obtain a global fuzzy simplicial sets. Both fuzzy set operations use the product t-norm. The value of this parameter should be between 0.0 and 1.0; a value of 1.0 will use a pure fuzzy union, while 0.0 will

use a pure fuzzy intersection.

local.connectivity

The local connectivity required - i.e. the number of nearest neighbors that should be assumed to be connected at a local level. The higher this value the more connected the manifold becomes locally. In practice this should be not more than the local intrinsic dimension of the manifold.

repulsion.strength

Weighting applied to negative samples in low dimensional embedding optimization. Values higher than one will result in greater weight being given to negative samples.

negative.sample.rate

а

The number of negative samples to select per positive sample in the optimization process. Increasing this value will result in greater repulsive force being applied, greater optimization cost, but slightly more accuracy.

More specific parameters controlling the embedding. If NULL, these values are set automatically as determined by min. dist and spread. Parameter of differen-

tiable approximation of right adjoint functor.

b More specific parameters controlling the embedding. If NULL, these values are set automatically as determined by min. dist and spread. Parameter of differen-

tiable approximation of right adjoint functor.

uwot.sgd Set uwot::umap(fast\_sgd = TRUE); see umap for more details

seed.use Set a random seed. By default, sets the seed to 42. Setting NULL will not set a

seed

metric.kwds A dictionary of arguments to pass on to the metric, such as the p value for

Minkowski distance. If NULL then no arguments are passed on.

angular.rp.forest

Whether to use an angular random projection forest to initialise the approximate nearest neighbor search. This can be faster, but is mostly on useful for metric that use an angular style distance such as cosine, correlation etc. In the case of

those metrics angular forests will be chosen automatically.

densmap Whether to use the density-augmented objective of densMAP. Turning on this

option generates an embedding where the local densities are encouraged to be correlated with those in the original space. Parameters below with the prefix 'dens' further control the behavior of this extension. Default is FALSE. Only

compatible with 'umap-learn' method and version of umap-learn >= 0.5.0

dens.lambda Specific parameter which controls the regularization weight of the density cor-

relation term in densMAP. Higher values prioritize density preservation over the UMAP objective, and vice versa for values closer to zero. Setting this parameter to zero is equivalent to running the original UMAP algorithm. Default value is

2.

dens.frac Specific parameter which controls the fraction of epochs (between 0 and 1)

where the density-augmented objective is used in densMAP. The first (1 - dens\_frac) fraction of epochs optimize the original UMAP objective before introducing the

density correlation term. Default is 0.3.

dens.var.shift Specific parameter which specifies a small constant added to the variance of

local radii in the embedding when calculating the density correlation objective to prevent numerical instability from dividing by a small number. Default is 0.1.

verbose Controls verbosity

densmap.kwds A dictionary of arguments to pass on to the densMAP optimization.

dims Which dimensions to use as input features, used only if features is NULL

reduction Which dimensional reduction (PCA or ICA) to use for the UMAP input. Default

is PCA

features If set, run UMAP on this subset of features (instead of running on a set of re-

duced dimensions). Not set (NULL) by default; dims must be NULL to run on

features

graph Name of graph on which to run UMAP

nn.name Name of knn output on which to run UMAP

slot The slot used to pull data for when using features. data slot is by default.

reduction.name Name to store dimensional reduction under in the Seurat object

#### Value

Returns a Seurat object containing a UMAP representation

192 SampleUMI

#### References

McInnes, L, Healy, J, UMAP: Uniform Manifold Approximation and Projection for Dimension Reduction, ArXiv e-prints 1802.03426, 2018

#### **Examples**

```
## Not run:
data("pbmc_small")
pbmc_small
# Run UMAP map on first 5 PCs
pbmc_small <- RunUMAP(object = pbmc_small, dims = 1:5)
# Plot results
DimPlot(object = pbmc_small, reduction = 'umap')
## End(Not run)</pre>
```

SampleUMI

Sample UMI

### **Description**

Downsample each cell to a specified number of UMIs. Includes an option to upsample cells below specified UMI as well.

# Usage

```
SampleUMI(data, max.umi = 1000, upsample = FALSE, verbose = FALSE)
```

# Arguments

data Matrix with the raw count data max.umi Number of UMIs to sample to

upsample Upsamples all cells with fewer than max.umi

verbose Display the progress bar

#### Value

Matrix with downsampled data

### **Examples**

```
data("pbmc_small")
counts = as.matrix(x = GetAssayData(object = pbmc_small, assay = "RNA", slot = "counts"))
downsampled = SampleUMI(data = counts)
head(x = downsampled)
```

SaveAnnoyIndex 193

 ${\tt SaveAnnoyIndex}$ 

Save the Annoy index

### **Description**

Save the Annoy index

### Usage

```
SaveAnnoyIndex(object, file)
```

### Arguments

object A Neighbor object with the annoy index stored

file Path to file to write index to

ScaleData

Scale and center the data.

### **Description**

Scales and centers features in the dataset. If variables are provided in vars.to.regress, they are individually regressed against each feature, and the resulting residuals are then scaled and centered.

```
ScaleData(object, ...)
## Default S3 method:
ScaleData(
  object,
  features = NULL,
  vars.to.regress = NULL,
  latent.data = NULL,
  split.by = NULL,
  model.use = "linear",
  use.umi = FALSE,
  do.scale = TRUE,
  do.center = TRUE,
  scale.max = 10,
  block.size = 1000,
 min.cells.to.block = 3000,
  verbose = TRUE,
)
```

194 ScaleData

```
## S3 method for class 'Assay'
ScaleData(
  object,
  features = NULL,
  vars.to.regress = NULL,
 latent.data = NULL,
  split.by = NULL,
 model.use = "linear",
 use.umi = FALSE,
  do.scale = TRUE,
  do.center = TRUE,
  scale.max = 10,
 block.size = 1000,
 min.cells.to.block = 3000,
  verbose = TRUE,
)
## S3 method for class 'Seurat'
ScaleData(
 object,
  features = NULL,
  assay = NULL,
 vars.to.regress = NULL,
  split.by = NULL,
 model.use = "linear",
 use.umi = FALSE,
 do.scale = TRUE,
 do.center = TRUE,
  scale.max = 10,
 block.size = 1000,
 min.cells.to.block = 3000,
  verbose = TRUE,
)
```

### Arguments

object An object

Arguments passed to other methods

features Vector of features names to scale/center. Default is variable features.

Variables to regress out (previously latent.vars in RegressOut). For example, nUMI, or percent.mito.

latent.data Extra data to regress out, should be cells x latent data

split.by Name of variable in object metadata or a vector or factor defining grouping of cells. See argument f in split for more details

ScaleFactors 195

| model.use Use a linear model or generalized linear model (poisson, negative bir the regression. Options are 'linear' (default), 'poisson', and 'negbino |                                                                                                                                                                                                                                                           |  |  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| use.umi                                                                                                                                                 | Regress on UMI count data. Default is FALSE for linear modeling, but automatically set to TRUE if model.use is 'negbinom' or 'poisson'                                                                                                                    |  |  |
| do.scale Whether to scale the data.                                                                                                                     |                                                                                                                                                                                                                                                           |  |  |
| do.center                                                                                                                                               | Whether to center the data.                                                                                                                                                                                                                               |  |  |
| scale.max                                                                                                                                               | Max value to return for scaled data. The default is 10. Setting this can help reduce the effects of features that are only expressed in a very small number of cells. If regressing out latent variables and using a non-linear model, the default is 50. |  |  |
| block.size                                                                                                                                              | Default size for number of features to scale at in a single computation. Increasing block.size may speed up calculations but at an additional memory cost.                                                                                                |  |  |
| min.cells.to.block                                                                                                                                      |                                                                                                                                                                                                                                                           |  |  |
|                                                                                                                                                         | If object contains fewer than this number of cells, don't block for scaling calculations.                                                                                                                                                                 |  |  |
| verbose                                                                                                                                                 | Displays a progress bar for scaling procedure                                                                                                                                                                                                             |  |  |
| assay                                                                                                                                                   | Name of Assay to scale                                                                                                                                                                                                                                    |  |  |

#### **Details**

ScaleData now incorporates the functionality of the function formerly known as RegressOut (which regressed out given the effects of provided variables and then scaled the residuals). To make use of the regression functionality, simply pass the variables you want to remove to the vars.to.regress parameter.

Setting center to TRUE will center the expression for each feature by subtracting the average expression for that feature. Setting scale to TRUE will scale the expression level for each feature by dividing the centered feature expression levels by their standard deviations if center is TRUE and by their root mean square otherwise.

ScaleFactors

Get image scale factors

# Description

Get image scale factors

```
ScaleFactors(object, ...)
scalefactors(spot, fiducial, hires, lowres)
## S3 method for class 'VisiumV1'
ScaleFactors(object, ...)
## S3 method for class 'VisiumV1'
ScaleFactors(object, ...)
```

196 ScoreJackStraw

## Arguments

| object   | An object to get scale factors from   |  |
|----------|---------------------------------------|--|
|          | Arguments passed to other methods     |  |
| spot     | Spot full resolution scale factor     |  |
| fiducial | Fiducial full resolution scale factor |  |
| hires    | High resolutoin scale factor          |  |
| lowres   | Low resolution scale factor           |  |

### Value

An object of class scalefactors

#### Note

scalefactors objects can be created with scalefactors()

ScoreJackStraw

Compute Jackstraw scores significance.

### Description

Significant PCs should show a p-value distribution that is strongly skewed to the left compared to the null distribution. The p-value for each PC is based on a proportion test comparing the number of features with a p-value below a particular threshold (score.thresh), compared with the proportion of features expected under a uniform distribution of p-values.

```
ScoreJackStraw(object, ...)
## S3 method for class 'JackStrawData'
ScoreJackStraw(object, dims = 1:5, score.thresh = 1e-05, ...)
## S3 method for class 'DimReduc'
ScoreJackStraw(object, dims = 1:5, score.thresh = 1e-05, ...)
## S3 method for class 'Seurat'
ScoreJackStraw(
   object,
   reduction = "pca",
   dims = 1:5,
   score.thresh = 1e-05,
   do.plot = FALSE,
   ...
)
```

SCTAssay-class 197

#### **Arguments**

object An object

... Arguments passed to other methods

dims Which dimensions to examine

score.thresh Threshold to use for the proportion test of PC significance (see Details)

reduction Reduction associated with JackStraw to score

do.plot Show plot. To return ggplot object, use JackStrawPlot after running Score-

JackStraw.

#### Value

Returns a Seurat object

JackStrawPlot

SCTAssay-class

The SCTModel Class

# Description

The SCTModel object is a model and parameters storage from SCTransform. It can be used to calculate Pearson residuals for new genes.

The SCTAssay object contains all the information found in an Assay object, with extra information from the results of SCTransform

#### Usage

```
## S3 method for class 'SCTAssay'
levels(x)
## S3 replacement method for class 'SCTAssay'
levels(x) <- value</pre>
```

## Arguments

x An SCTAssay object

value New levels, must be in the same order as the levels present

198 SCTAssay-class

#### Value

```
levels: SCT model names
levels<-: x with updated SCT model names
```

#### **Slots**

feature.attributes A data.frame with feature attributes in SCTransform cell.attributes A data.frame with cell attributes in SCTransform

clips A list of two numeric of length two specifying the min and max values the Pearson residual will be clipped to. One for vst and one for SCTransform

umi.assay Name of the assay of the seurat object containing UMI matrix and the default is RNA model A formula used in SCTransform

arguments other information used in SCTransform

median\_umi Median UMI (or scale factor) used to calculate corrected counts

SCTModel.list A list containing SCT models

### Get and set SCT model names

SCT results are named by initial run of SCTransform in order to keep SCT parameters straight between runs. When working with merged SCTAssay objects, these model names are important. levels allows querying the models present. levels<- allows the changing of the names of the models present, useful when merging SCTAssay objects. Note: unlike normal levels<-, levels<-.SCTAssay allows complete changing of model names, not reordering.

#### Creating an SCTAssay from an Assay

Conversion from an Assay object to an SCTAssay object by is done by adding the additional slots to the object. If from has results generated by SCTransform from Seurat v3.0.0 to v3.1.1, the conversion will automagically fill the new slots with the data

#### See Also

Assay Assay

### **Examples**

```
## Not run:
# SCTAssay objects are generated from SCTransform
pbmc_small <- SCTransform(pbmc_small)

## End(Not run)

# SCTAssay objects are generated from SCTransform
pbmc_small <- SCTransform(pbmc_small)
pbmc_small[["SCT"]]</pre>
```

SCTransform 199

```
## Not run:
# Query and change SCT model names
levels(pbmc_small[['SCT']])
levels(pbmc_small[['SCT']]) <- '3'
levels(pbmc_small[['SCT']])
## End(Not run)</pre>
```

SCTransform

Use regularized negative binomial regression to normalize UMI count data

### **Description**

This function calls sctransform::vst. The sctransform package is available at https://github.com/ChristophH/sctransform. Use this function as an alternative to the NormalizeData, FindVariableFeatures, ScaleData workflow. Results are saved in a new assay (named SCT by default) with counts being (corrected) counts, data being log1p(counts), scale.data being pearson residuals; sctransform::vst intermediate results are saved in misc slot of new assay.

```
SCTransform(
  object,
  assay = "RNA",
  new.assay.name = "SCT",
  reference.SCT.model = NULL,
  do.correct.umi = TRUE,
  ncells = 5000,
  residual.features = NULL,
  variable.features.n = 3000,
  variable.features.rv.th = 1.3,
  vars.to.regress = NULL,
  do.scale = FALSE,
  do.center = TRUE,
  clip.range = c(-sqrt(x = ncol(x = object[[assay]])/30), sqrt(x = ncol(x = object[[assay]])/30)
    object[[assay]])/30)),
  conserve.memory = FALSE,
  return.only.var.genes = TRUE,
  seed.use = 1448145,
  verbose = TRUE,
)
```

200 SCTransform

#### **Arguments**

object A seurat object

assay Name of assay to pull the count data from; default is 'RNA' new.assay.name Name for the new assay containing the normalized data

reference.SCT.model

If not NULL, compute residuals for the object using the provided SCT model; supports only log\_umi as the latent variable. If residual.features are not specified, compute for the top variable.features.n specified in the model which are also present in the object. If residual.features are specified, the variable features of the resulting SCT assay are set to the top variable.features.n in the model.

do.correct.umi Place corrected UMI matrix in assay counts slot; default is TRUE

ncells Number of subsampling cells used to build NB regression; default is 5000 residual.features

Genes to calculate residual features for; default is NULL (all genes). If specified, will be set to VariableFeatures of the returned object.

variable.features.n

Use this many features as variable features after ranking by residual variance; default is 3000. Only applied if residual.features is not set.

variable.features.rv.th

Instead of setting a fixed number of variable features, use this residual variance cutoff; this is only used when variable. features.n is set to NULL; default is 1.3. Only applied if residual.features is not set.

vars.to.regress

Variables to regress out in a second non-regularized linear regression. For example, percent.mito. Default is NULL

do.scale Whether to scale residuals to have unit variance; default is FALSE do.center Whether to center residuals to have mean zero; default is TRUE

clip.range Range to clip the residuals to; default is c(-sqrt(n/30), sqrt(n/30)), where

n is the number of cells

conserve.memory

If set to TRUE the residual matrix for all genes is never created in full; useful for large data sets, but will take longer to run; this will also set return.only.var.genes to TRUE; default is FALSE

return.only.var.genes

If set to TRUE the scale.data matrices in output assay are subset to contain only

the variable genes; default is TRUE

seed.use Set a random seed. By default, sets the seed to 1448145. Setting NULL will not

set a seed.

verbose Whether to print messages and progress bars

... Additional parameters passed to sctransform::vst

#### Value

Returns a Seurat object with a new assay (named SCT by default) with counts being (corrected) counts, data being log1p(counts), scale.data being pearson residuals; sctransform::vst intermediate results are saved in misc slot of the new assay.

SCTResults 201

#### See Also

```
correct_counts get_residuals
```

### **Examples**

```
data("pbmc_small")
SCTransform(object = pbmc_small)
```

SCTResults

Get SCT results from an Assay

# Description

Pull the SCTResults information from an SCTAssay object.

### Usage

```
SCTResults(object, ...)
SCTResults(object, ...) <- value

## S3 method for class 'SCTModel'
SCTResults(object, slot, ...)

## S3 replacement method for class 'SCTModel'
SCTResults(object, slot, ...) <- value

## S3 method for class 'SCTAssay'
SCTResults(object, slot, model = NULL, ...)

## S3 replacement method for class 'SCTAssay'
SCTResults(object, slot, model = NULL, ...) <- value

## S3 method for class 'Seurat'
SCTResults(object, assay = "SCT", slot, model = NULL, ...)</pre>
```

### **Arguments**

| object | An object                                                                          |  |
|--------|------------------------------------------------------------------------------------|--|
|        | Arguments passed to other methods (not used)                                       |  |
| value  | new data to set                                                                    |  |
| slot   | Which slot to pull the SCT results from                                            |  |
| model  | Name of SCModel to pull result from. Available names can be retrieved with levels. |  |
| assay  | Assay in the Seurat object to pull from                                            |  |

#### Value

Returns the value present in the requested slot for the requested group. If group is not specified, returns a list of slot results for each group unless there is only one group present (in which case it just returns the slot directly).

SelectIntegrationFeatures

Select integration features

### **Description**

Choose the features to use when integrating multiple datasets. This function ranks features by the number of datasets they are deemed variable in, breaking ties by the median variable feature rank across datasets. It returns the top scoring features by this ranking.

### Usage

```
SelectIntegrationFeatures(
  object.list,
  nfeatures = 2000,
  assay = NULL,
  verbose = TRUE,
  fvf.nfeatures = 2000,
  ...
)
```

## **Arguments**

object.list List of seurat objects

nfeatures Number of features to return

assay Name or vector of assay names (one for each object) from which to pull the

variable features.

verbose Print messages

fvf.nfeatures nfeatures for FindVariableFeatures. Used if VariableFeatures have not

been set for any object in object.list.

... Additional parameters to FindVariableFeatures

### **Details**

If for any assay in the list, FindVariableFeatures hasn't been run, this method will try to run it using the fvf.nfeatures parameter and any additional ones specified through the ....

#### Value

A vector of selected features

SetIntegrationData 203

#### **Examples**

```
## Not run:
# to install the SeuratData package see https://github.com/satijalab/seurat-data
library(SeuratData)
data("panc8")

# panc8 is a merged Seurat object containing 8 separate pancreas datasets
# split the object by dataset and take the first 2
pancreas.list <- SplitObject(panc8, split.by = "tech")[1:2]

# perform SCTransform normalization
pancreas.list <- lapply(X = pancreas.list, FUN = SCTransform)

# select integration features
features <- SelectIntegrationFeatures(pancreas.list)

## End(Not run)</pre>
```

 ${\tt SetIntegrationData}$ 

Set integration data

### **Description**

Set integration data

### Usage

```
SetIntegrationData(object, integration.name, slot, new.data)
```

### **Arguments**

object Seurat object

integration.name

Name of integration object

slot Which slot in integration object to set

new.data New data to insert

#### Value

Returns a Seurat object

204 Seurat-class

SetQuantile

Find the Quantile of Data

### **Description**

Converts a quantile in character form to a number regarding some data. String form for a quantile is represented as a number prefixed with "q"; for example, 10th quantile is "q10" while 2nd quantile is "q2". Will only take a quantile of non-zero data values

## Usage

```
SetQuantile(cutoff, data)
```

### **Arguments**

cutoff The cutoff to turn into a quantile
data The data to turn find the quantile of

#### Value

The numerical representation of the quantile

# Examples

```
set.seed(42)
SetQuantile('q10', sample(1:100, 10))
```

Seurat-class

The Seurat Class

### **Description**

The Seurat object is a representation of single-cell expression data for R; for more details, please see the documentation in SeuratObject

SeuratTheme

Seurat Themes

### **Description**

Various themes to be applied to ggplot2-based plots

SeuratTheme The curated Seurat theme, consists of ...

DarkTheme A dark theme, axes and text turn to white, the background becomes black

NoAxes Removes axis lines, text, and ticks

NoLegend Removes the legend

FontSize Sets axis and title font sizes

NoGrid Removes grid lines

SeuratAxes Set Seurat-style axes

SpatialTheme A theme designed for spatial visualizations (eg PolyFeaturePlot, PolyDimPlot)

RestoreLegend Restore a legend after removal

RotatedAxis Rotate X axis text 45 degrees

BoldTitle Enlarges and emphasizes the title

```
SeuratTheme()
CenterTitle(...)
DarkTheme(...)
FontSize(
   x.text = NULL,
   y.text = NULL,
   x.title = NULL,
   y.title = NULL,
```

206 SeuratTheme

```
main = NULL,
    )
    NoAxes(..., keep.text = FALSE, keep.ticks = FALSE)
    NoLegend(...)
    NoGrid(...)
    SeuratAxes(...)
    SpatialTheme(...)
    RestoreLegend(..., position = "right")
    RotatedAxis(...)
    BoldTitle(...)
    WhiteBackground(...)
Arguments
                     Extra parameters to be passed to theme
    x.text, y.text X and Y axis text sizes
    x.title, y.title
                      X and Y axis title sizes
                     Plot title size
    main
    keep.text
                      Keep axis text
    keep.ticks
                      Keep axis ticks
    position
                     A position to restore the legend to
Value
    A ggplot2 theme object
See Also
    theme
Examples
    # Generate a plot with a dark theme
    library(ggplot2)
    df \leftarrow data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
    p \leftarrow gplot(data = df, mapping = aes(x = x, y = y)) + geom_point(mapping = aes(color = 'red'))
    p + DarkTheme(legend.position = 'none')
```

SlideSeq-class 207

```
# Generate a plot with no axes
library(ggplot2)
df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
p <- ggplot(data = df, mapping = aes(x = x, y = y)) + geom_point(mapping = aes(color = 'red'))
p + NoAxes()

# Generate a plot with no legend
library(ggplot2)
df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
p <- ggplot(data = df, mapping = aes(x = x, y = y)) + geom_point(mapping = aes(color = 'red'))
p + NoLegend()

# Generate a plot with no grid lines
library(ggplot2)
df <- data.frame(x = rnorm(n = 100, mean = 20, sd = 2), y = rbinom(n = 100, size = 100, prob = 0.2))
p <- ggplot(data = df, mapping = aes(x = x, y = y)) + geom_point(mapping = aes(color = 'red'))
p <- ggplot(data = df, mapping = aes(x = x, y = y)) + geom_point(mapping = aes(color = 'red'))
p + NoGrid()</pre>
```

SlideSeq-class

The SlideSeq class

## Description

The SlideSeq class represents spatial information from the Slide-seq platform

# Slots

coordinates ...

#### **Slots**

assay Name of assay to associate image data with; will give this image priority for visualization when the assay is set as the active/default assay in a Seurat object

key Key for the image

SpatialImage-class

The SpatialImage Class

#### **Description**

For more details, please see the documentation in SeuratObject

### See Also

SeuratObject::SpatialImage-class

208 SpatialPlot

SpatialPlot

Visualize spatial clustering and expression data.

#### **Description**

SpatialPlot plots a feature or discrete grouping (e.g. cluster assignments) as spots over the image that was collected. We also provide SpatialFeaturePlot and SpatialDimPlot as wrapper functions around SpatialPlot for a consistent naming framework.

```
SpatialPlot(
  object,
  group.by = NULL,
  features = NULL,
  images = NULL,
  cols = NULL,
  image.alpha = 1,
  crop = TRUE,
  slot = "data",
 min.cutoff = NA,
 max.cutoff = NA,
  cells.highlight = NULL,
  cols.highlight = c("#DE2D26", "grey50"),
  facet.highlight = FALSE,
  label = FALSE,
  label.size = 5,
  label.color = "white",
  label.box = TRUE,
  repel = FALSE,
  ncol = NULL,
  combine = TRUE,
  pt.size.factor = 1.6,
  alpha = c(1, 1),
  stroke = 0.25,
  interactive = FALSE,
  do.identify = FALSE,
  identify.ident = NULL,
  do.hover = FALSE,
  information = NULL
)
SpatialDimPlot(
  object,
  group.by = NULL,
  images = NULL,
  cols = NULL,
```

SpatialPlot 209

```
crop = TRUE,
  cells.highlight = NULL,
  cols.highlight = c("#DE2D26", "grey50"),
  facet.highlight = FALSE,
 label = FALSE,
 label.size = 7,
 label.color = "white",
  repel = FALSE,
 ncol = NULL,
 combine = TRUE,
 pt.size.factor = 1.6,
 alpha = c(1, 1),
  image.alpha = 1,
  stroke = 0.25,
  label.box = TRUE,
  interactive = FALSE,
  information = NULL
)
SpatialFeaturePlot(
 object,
 features,
  images = NULL,
 crop = TRUE,
 slot = "data",

 max.cutoff = NA,
 ncol = NULL,
 combine = TRUE,
 pt.size.factor = 1.6,
 alpha = c(1, 1),
  image.alpha = 1,
  stroke = 0.25,
  interactive = FALSE,
  information = NULL
)
```

#### **Arguments**

| object                                                                                | A Seurat object                                                                                                                                                                                                    |  |
|---------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| group.by Name of meta.data column to group the data by                                |                                                                                                                                                                                                                    |  |
| features Name of the feature to visualize. Provide either group.by OR features, not b |                                                                                                                                                                                                                    |  |
| images Name of the images to use in the plot(s)                                       |                                                                                                                                                                                                                    |  |
| cols                                                                                  | Vector of colors, each color corresponds to an identity class. This may also be a single character or numeric value corresponding to a palette as specified by brewer.pal.info. By default, ggplot2 assigns colors |  |
| image.alpha                                                                           | Adjust the opacity of the background images. Set to 0 to remove.                                                                                                                                                   |  |

210 SpatialPlot

crop Crop the plot in to focus on points plotted. Set to FALSE to show entire back-

ground image.

slot If plotting a feature, which data slot to pull from (counts, data, or scale.data)

min.cutoff, max.cutoff

Vector of minimum and maximum cutoff values for each feature, may specify

quantile in the form of 'q##' where '##' is the quantile (eg, 'q1', 'q10')

cells.highlight

A list of character or numeric vectors of cells to highlight. If only one group of

cells desired, can simply pass a vector instead of a list. If set, colors selected

cells to the color(s) in cols.highlight

cols.highlight A vector of colors to highlight the cells as; ordered the same as the groups in

cells.highlight; last color corresponds to unselected cells.

facet.highlight

When highlighting certain groups of cells, split each group into its own plot

label Whether to label the clusters

label.size Sets the size of the labels

label.color Sets the color of the label text

label.box Whether to put a box around the label text (geom\_text vs geom\_label)

repel Repels the labels to prevent overlap

ncol Number of columns if plotting multiple plots

combine Combine plots into a single gg object; note that if TRUE; themeing will not

work when plotting multiple features/groupings

pt.size.factor Scale the size of the spots.

alpha Controls opacity of spots. Provide as a vector specifying the min and max for

SpatialFeaturePlot. For SpatialDimPlot, provide a single alpha value for each

plot.

stroke Control the width of the border around the spots

interactive Launch an interactive SpatialDimPlot or SpatialFeaturePlot session, see ISpatialDimPlot

or ISpatialFeaturePlot for more details

do.identify, do.hover

DEPRECATED in favor of interactive

identify.ident DEPRECATED

information An optional dataframe or matrix of extra information to be displayed on hover

#### Value

If do.identify, either a vector of cells selected or the object with selected cells set to the value of identify.ident (if set). Else, if do.hover, a plotly object with interactive graphics. Else, a ggplot object

SplitObject 211

#### **Examples**

```
## Not run:
# For functionality analagous to FeaturePlot
SpatialPlot(seurat.object, features = "MS4A1")
SpatialFeaturePlot(seurat.object, features = "MS4A1")
# For functionality analagous to DimPlot
SpatialPlot(seurat.object, group.by = "clusters")
SpatialDimPlot(seurat.object, group.by = "clusters")
## End(Not run)
```

SplitObject

Splits object into a list of subsetted objects.

## Description

Splits object based on a single attribute into a list of subsetted objects, one for each level of the attribute. For example, useful for taking an object that contains cells from many patients, and subdividing it into patient-specific objects.

#### Usage

```
SplitObject(object, split.by = "ident")
```

# **Arguments**

object Seurat object

split.by Attribute for splitting. Default is "ident". Currently only supported for class-

level (i.e. non-quantitative) attributes.

#### Value

A named list of Seurat objects, each containing a subset of cells from the original object.

# **Examples**

```
data("pbmc_small")
# Assign the test object a three level attribute
groups <- sample(c("group1", "group2", "group3"), size = 80, replace = TRUE)
names(groups) <- colnames(pbmc_small)
pbmc_small <- AddMetaData(object = pbmc_small, metadata = groups, col.name = "group")
obj.list <- SplitObject(pbmc_small, split.by = "group")</pre>
```

212 subset,AnchorSet

STARmap-class

The STARmap class

### **Description**

The STARmap class

#### **Slots**

assay Name of assay to associate image data with; will give this image priority for visualization when the assay is set as the active/default assay in a Seurat object

key Key for the image

subset.AnchorSet

Subset an AnchorSet object

### **Description**

Subset an AnchorSet object

#### Usage

```
## $3 method for class 'AnchorSet'
subset(
    x,
    score.threshold = NULL,
    disallowed.dataset.pairs = NULL,
    dataset.matrix = NULL,
    group.by = NULL,
    disallowed.ident.pairs = NULL,
    ident.matrix = NULL,
    ...
)
```

### Arguments

```
x object to be subsetted.
```

score.threshold

Only anchor pairs with scores greater than this value are retained.

disallowed.dataset.pairs

Remove any anchors formed between the provided pairs. E.g. list(c(1, 5), c(1, 2)) filters out any anchors between datasets 1 and 5 and datasets 1 and 2.

dataset.matrix Provide a binary matrix specifying whether a dataset pair is allowable (1) or not (0). Should be a dataset x dataset matrix.

group.by Grouping variable to determine allowable ident pairs

disallowed.ident.pairs

Remove any anchors formed between provided ident pairs. E.g. list(c("CD4",

"CD8"), c("B-cell", "T-cell"))

ident.matrix Provide a binary matrix specifying whether an ident pair is allowable (1) or not

(0). Should be an ident x ident symmetric matrix

.. further arguments to be passed to or from other methods.

#### Value

Returns an AnchorSet object with specified anchors filtered out

 ${\tt SubsetByBarcodeInflections}$ 

Subset a Seurat Object based on the Barcode Distribution Inflection Points

### **Description**

This convenience function subsets a Seurat object based on calculated inflection points.

### Usage

SubsetByBarcodeInflections(object)

# Arguments

object Seurat object

#### **Details**

See [CalculateBarcodeInflections()] to calculate inflection points and [BarcodeInflectionsPlot()] to visualize and test inflection point calculations.

### Value

Returns a subsetted Seurat object.

#### Author(s)

Robert A. Amezquita, <robert.amezquita@fredhutch.org>

#### See Also

 ${\tt CalculateBarcodeInflections\,BarcodeInflectionsPlot}$ 

TopCells TopCells

#### **Examples**

```
data("pbmc_small")
pbmc_small <- CalculateBarcodeInflections(
   object = pbmc_small,
   group.column = 'groups',
   threshold.low = 20,
   threshold.high = 30
)
SubsetByBarcodeInflections(object = pbmc_small)</pre>
```

TopCells

Find cells with highest scores for a given dimensional reduction technique

### **Description**

Return a list of genes with the strongest contribution to a set of components

#### Usage

```
TopCells(object, dim = 1, ncells = 20, balanced = FALSE, ...)
```

## Arguments

object DimReduc object dim Dimension to use

ncells Number of cells to return

balanced Return an equal number of cells with both + and - scores.

... Extra parameters passed to Embeddings

### Value

Returns a vector of cells

### **Examples**

```
data("pbmc_small")
pbmc_small
head(TopCells(object = pbmc_small[["pca"]]))
# Can specify which dimension and how many cells to return
TopCells(object = pbmc_small[["pca"]], dim = 2, ncells = 5)
```

TopFeatures 215

| TopFeatures | Find features with highest scores for a given dimensional reduction technique |
|-------------|-------------------------------------------------------------------------------|
|             |                                                                               |

# Description

Return a list of features with the strongest contribution to a set of components

# Usage

```
TopFeatures(
  object,
  dim = 1,
  nfeatures = 20,
  projected = FALSE,
  balanced = FALSE,
  ...
)
```

# Arguments

| object                                                        | DimReduc object                     |
|---------------------------------------------------------------|-------------------------------------|
| dim                                                           | Dimension to use                    |
| nfeatures                                                     | Number of features to return        |
| projected                                                     | Use the projected feature loadings  |
| balanced Return an equal number of features with both + and - |                                     |
|                                                               | Extra parameters passed to Loadings |

### Value

Returns a vector of features

# Examples

```
data("pbmc_small")
pbmc_small
TopFeatures(object = pbmc_small[["pca"]], dim = 1)
# After projection:
TopFeatures(object = pbmc_small[["pca"]], dim = 1, projected = TRUE)
```

| 101 | JI 10 1 | اجاللا | JUI 3 |

Get nearest neighbors for given cell

### **Description**

Return a vector of cell names of the nearest n cells.

# Usage

```
TopNeighbors(object, cell, n = 5)
```

### **Arguments**

object Neighbor object cell Cell of interest

n Number of neighbors to return

#### Value

Returns a vector of cell names

TransferAnchorSet-class

The TransferAnchorSet Class

# Description

Inherits from the Anchorset class. Implemented mainly for method dispatch purposes. See AnchorSet for slot details.

TransferData

Transfer data

# Description

Transfer categorical or continuous data across single-cell datasets. For transferring categorical information, pass a vector from the reference dataset (e.g. refdata = reference\$celltype). For transferring continuous information, pass a matrix from the reference dataset (e.g. refdata = GetAssayData(reference[['RNA']])).

TransferData 217

#### Usage

```
TransferData(
  anchorset,
  refdata,
  reference = NULL,
  query = NULL,
 weight.reduction = "pcaproject",
  12.norm = FALSE,
  dims = NULL,
  k.weight = 50,
  sd.weight = 1,
  eps = 0,
  n.trees = 50,
  verbose = TRUE,
  slot = "data",
 prediction.assay = FALSE,
  store.weights = TRUE
)
```

#### **Arguments**

anchorset

An AnchorSet object generated by FindTransferAnchors

refdata

Data to transfer. This can be specified in one of two ways:

- The reference data itself as either a vector where the names correspond to the reference cells, or a matrix, where the column names correspond to the reference cells.
- The name of the metadata field or assay from the reference object provided. This requires the reference parameter to be specified. If pulling assay data in this manner, it will pull the data from the data slot. To transfer data from other slots, please pull the data explicitly with GetAssayData and provide that matrix here.

reference

Reference object from which to pull data to transfer

query

Query object into which the data will be transferred.

weight.reduction

Dimensional reduction to use for the weighting anchors. Options are:

- pcaproject: Use the projected PCA used for anchor building
- lsiproject: Use the projected LSI used for anchor building
- pca: Use an internal PCA on the query only
- cca: Use the CCA used for anchor building
- custom DimReduc: User provided DimReduc object computed on the query cells

12.norm

Perform L2 normalization on the cell embeddings after dimensional reduction

dims

Set of dimensions to use in the anchor weighting procedure. If NULL, the same dimensions that were used to find anchors will be used for weighting.

k.weight

Number of neighbors to consider when weighting anchors

218 TransferData

sd.weight Controls the bandwidth of the Gaussian kernel for weighting eps Error bound on the neighbor finding algorithm (from RANN)

n.trees More trees gives higher precision when using annoy approximate nearest neigh-

bor search

verbose Print progress bars and output

slot Slot to store the imputed data. Must be either "data" (default) or "counts"

prediction.assay

Return an Assay object with the prediction scores for each class stored in the

data slot.

store.weights Optionally store the weights matrix used for predictions in the returned query

object.

#### **Details**

The main steps of this procedure are outlined below. For a more detailed description of the methodology, please see Stuart, Butler, et al Cell 2019. doi:10.1016/j.cell.2019.05.031; doi:10.1101/460147

For both transferring discrete labels and also feature imputation, we first compute the weights matrix.

• Construct a weights matrix that defines the association between each query cell and each anchor. These weights are computed as 1 - the distance between the query cell and the anchor divided by the distance of the query cell to the k.weightth anchor multiplied by the anchor score computed in FindIntegrationAnchors. We then apply a Gaussian kernel width a bandwidth defined by sd.weight and normalize across all k.weight anchors.

The main difference between label transfer (classification) and feature imputation is what gets multiplied by the weights matrix. For label transfer, we perform the following steps:

- Create a binary classification matrix, the rows corresponding to each possible class and the columns corresponding to the anchors. If the reference cell in the anchor pair is a member of a certain class, that matrix entry is filled with a 1, otherwise 0.
- Multiply this classification matrix by the transpose of weights matrix to compute a prediction score for each class for each cell in the query dataset.

For feature imputation, we perform the following step:

Multiply the expression matrix for the reference anchor cells by the weights matrix. This returns a predicted expression matrix for the specified features for each cell in the query dataset.

#### Value

If query is not provided, for the categorical data in refdata, returns a data.frame with label predictions. If refdata is a matrix, returns an Assay object where the imputed data has been stored in the provided slot.

If query is provided, a modified query object is returned. For the categorical data in refdata, prediction scores are stored as Assays (prediction.score.NAME) and two additional metadata fields: predicted.NAME and predicted.NAME.score which contain the class prediction and the score for that predicted class. For continuous data, an Assay called NAME is returned. NAME here corresponds to the name of the element in the refdata list.

  pbmc.query <- AddMetaData(object = pbmc.query, metadata = predictions)</pre>
  ## End(Not run)
UpdateSCTAssays
                           Update pre-V4 Assays generated with SCTransform in the Seurat to
                           the new SCTAssay class
```

#### **Description**

Update pre-V4 Assays generated with SCTransform in the Seurat to the new SCTAssay class

#### Usage

```
UpdateSCTAssays(object)
```

#### **Arguments**

object A Seurat object

220 UpdateSymbolList

#### Value

A Seurat object with updated SCTAssays

UpdateSymbolList

Get updated synonyms for gene symbols

## Description

Find current gene symbols based on old or alias symbols using the gene names database from the HUGO Gene Nomenclature Committee (HGNC)

## Usage

```
GeneSymbolThesarus(
    symbols,
    timeout = 10,
    several.ok = FALSE,
    search.types = c("alias_symbol", "prev_symbol"),
    verbose = TRUE,
    ...
)

UpdateSymbolList(
    symbols,
    timeout = 10,
    several.ok = FALSE,
    verbose = TRUE,
    ...
)
```

## Arguments

| symbols      | A vector of gene symbols                                                                      |
|--------------|-----------------------------------------------------------------------------------------------|
| timeout      | Time to wait before canceling query in seconds                                                |
| several.ok   | Allow several current gene symbols for each provided symbol                                   |
| search.types | Type of query to perform:                                                                     |
|              | "alias_symbol" Find alternate symbols for the genes described by symbols                      |
|              | "prev_symbol" Find new new symbols for the genes described by symbols                         |
|              | This parameter accepts multiple options and short-hand options (eg. "prev" for "prev_symbol") |
| verbose      | Show a progress bar depicting search progress                                                 |
|              | Extra parameters passed to GET                                                                |

VariableFeaturePlot 221

#### **Details**

For each symbol passed, we query the HGNC gene names database for current symbols that have the provided symbol as either an alias (alias\_symbol) or old (prev\_symbol) symbol. All other queries are **not** supported.

#### Value

GeneSymbolThesarus:, if several.ok, a named list where each entry is the current symbol found for each symbol provided and the names are the provided symbols. Otherwise, a named vector with the same information.

UpdateSymbolList: symbols with updated symbols from HGNC's gene names database

#### Note

This function requires internet access

## Not run:
UpdateSymbolList(symbols = cc.genes$s.genes)
## End(Not run)
```

VariableFeaturePlot

View variable features

#### **Description**

View variable features

222 VariableFeaturePlot

#### Usage

```
VariableFeaturePlot(
  object,
  cols = c("black", "red"),
  pt.size = 1,
  log = NULL,
  selection.method = NULL,
  assay = NULL,
  raster = NULL,
  raster.dpi = c(512, 512)
)
```

#### Arguments

object Seurat object

cols Colors to specify non-variable/variable status

pt.size Size of the points on the plot log Plot the x-axis in log scale

selection.method

Which method to pull. For HVFInfo and VariableFeatures, choose one from one of the following:

- "vst"
- "sctransform" or "sct"
- "mean.var.plot", "dispersion", "mvp", or "disp"

For SVFInfo and Spatially Variable Features, choose from:

- "markvariogram"
- "moransi"

assay Assay to pull variable features from

raster Convert points to raster format, default is NULL which will automatically use

raster if the number of points plotted is greater than 100,000

raster.dpi Pixel resolution for rasterized plots, passed to geom\_scattermore(). Default is

c(512, 512).

#### Value

A ggplot object

### See Also

FindVariableFeatures

### **Examples**

```
data("pbmc_small")
VariableFeaturePlot(object = pbmc_small)
```

VisiumV1-class 223

VisiumV1-class Th

The VisiumV1 class

### **Description**

The VisiumV1 class represents spatial information from the 10X Genomics Visium platform

#### **Slots**

```
image A three-dimensional array with PNG image data, see readPNG for more details scale.factors An object of class scalefactors; see scalefactors for more information coordinates A data frame with tissue coordinate information spot.radius Single numeric value giving the radius of the spots
```

VizDimLoadings

Visualize Dimensional Reduction genes

#### **Description**

Visualize top genes associated with reduction components

#### Usage

```
VizDimLoadings(
  object,
  dims = 1:5,
  nfeatures = 30,
  col = "blue",
  reduction = "pca",
  projected = FALSE,
  balanced = FALSE,
  ncol = NULL,
  combine = TRUE
)
```

## **Arguments**

object Seurat object

dims Number of dimensions to display nfeatures Number of genes to display

col Color of points to use

reduction Reduction technique to visualize results for

224 VInPlot

projected Use reduction values for full dataset (i.e. projected dimensional reduction val-

ues)

balanced Return an equal number of genes with + and - scores. If FALSE (default), returns

the top genes ranked by the scores absolute values

ncol Number of columns to display

combine Combine plots into a single patchwork ggplot object. If FALSE, return a list of

ggplot objects

#### Value

A patchwork ggplot object if combine = TRUE; otherwise, a list of ggplot objects

## **Examples**

```
data("pbmc_small")
VizDimLoadings(object = pbmc_small)
```

VlnPlot

Single cell violin plot

#### **Description**

Draws a violin plot of single cell data (gene expression, metrics, PC scores, etc.)

#### Usage

```
VlnPlot(
  object,
  features,
  cols = NULL,
  pt.size = NULL,
  idents = NULL,
  sort = FALSE,
  assay = NULL,
  group.by = NULL,
  split.by = NULL,
  adjust = 1,
  y.max = NULL,
  same.y.lims = FALSE,
  log = FALSE,
  ncol = NULL,
  slot = "data",
  split.plot = FALSE,
  stack = FALSE,
  combine = TRUE,
  fill.by = "feature",
```

VlnPlot 225

```
flip = FALSE,
add.noise = TRUE,
raster = NULL
)
```

## Arguments

| object      | Seurat object                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| features    | Features to plot (gene expression, metrics, PC scores, anything that can be retreived by FetchData)                                                                |
| cols        | Colors to use for plotting                                                                                                                                         |
| pt.size     | Point size for geom_violin                                                                                                                                         |
| idents      | Which classes to include in the plot (default is all)                                                                                                              |
| sort        | Sort identity classes (on the x-axis) by the average expression of the attribute being potted, can also pass 'increasing' or 'decreasing' to change sort direction |
| assay       | Name of assay to use, defaults to the active assay                                                                                                                 |
| group.by    | Group (color) cells in different ways (for example, orig.ident)                                                                                                    |
| split.by    | A variable to split the violin plots by,                                                                                                                           |
| adjust      | Adjust parameter for geom_violin                                                                                                                                   |
| y.max       | Maximum y axis value                                                                                                                                               |
| same.y.lims | Set all the y-axis limits to the same values                                                                                                                       |
| log         | plot the feature axis on log scale                                                                                                                                 |
| ncol        | Number of columns if multiple plots are displayed                                                                                                                  |
| slot        | Slot to pull expression data from (e.g. "counts" or "data")                                                                                                        |
| split.plot  | plot each group of the split violin plots by multiple or single violin shapes.                                                                                     |
| stack       | Horizontally stack plots for each feature                                                                                                                          |
| combine     | Combine plots into a single patchworked ggplot object. If FALSE, return a list of ggplot                                                                           |
| fill.by     | Color violins/ridges based on either 'feature' or 'ident'                                                                                                          |
| flip        | flip plot orientation (identities on x-axis)                                                                                                                       |
| add.noise   | determine if adding a small noise for plotting                                                                                                                     |
| raster      | Convert points to raster format. Requires 'ggrastr' to be installed.                                                                                               |
|             |                                                                                                                                                                    |
